Abstract

Equal access to justice for people no matter their economic means is a fundamental value in organized societies, especially in democracies. Yet nations vary greatly in their commitment to providing that access to their lower income citizens. Some guarantee access to justice as a statutory or constitutional right and invest substantial public resources to supply subsidized lawyers to poor citizens, but many do not. Beyond the provision of subsidized counsel, other approaches for improving access to justice include contingent or conditional fees allowing lawyers to earn a percentage of their clients' recoveries while not charging if they lose; simplified procedures and/or laws that lessen the need for lawyers; substitution of lay advocates for lawyers in some forums; providing out-of-court assistance to allow disputants to represent themselves; and technologies that enhance access to justice in various ways.

History and political theory both underscore the fundamental importance of providing equal access to justice for all citizens no matter what their economic and social status. It was promised to the subjects of emperors and kings, and sometime delivered, long before those subjects began to even dream of the possibility of governing themselves. Then democratic theory, especially the social contract theory so influential with the founders of democracies in Europe and North America, emphasized that no man would surrender his natural right to resolve disputes through force unless government provided a forum to resolve those disputes where all citizens, rich and poor, had an equal chance of prevailing if in the right (Johnson, 2000, 2010). Thus, it is no surprise that constitutions and basic laws of nearly every democracy guarantee their citizens 'due process' or 'fair hearings' and 'equal protection of the laws' or 'equality before the law' (Johnson, 2000, 2010), as do multi-nation 'fundamental rights' agreements (European Convention on Human Rights and Fundamental Freedoms (1950), European Charter of Fundamental Rights (2009), and International Covenant on Civil and Political Rights of the United Nations (1966).)

Despite these solemn guarantees, however, for most democratic nations it was well into the twentieth century before governments became serious about offering their lower income citizens equal access to justice. Progress has been uneven, with some countries forging far ahead of others. This has become a field of study for political scientists, sociologists, historians, and legal scholars – seeking to analyze the problems, to devise solutions, to evaluate experimental approaches, to comprehend the political opposition to this goal, and to measure the progress.

Social scientists ponder how to measure the extent of need for legal services among low- and sometimes moderate-income people. Many countries have conducted survey research querying respondents about whether they have experienced common problems that experts have identified as being 'legal' or 'justiciable.' Although time frames for the studies varied, the percentage of people reporting at least one eligible problem ranged from a low of 19.5% in Japan to a high of 67% in the Netherlands, with Scotland, New Zealand, the UK, Northern Ireland, and the US in between (Currie, 2007). All these studies reflect that many respondents experienced more than one such 'legal' or 'justiciable' problem during the relevant time frame – some of them several such problems (see, e.g., American Bar Association, 1994; Currie, 2007).

These studies appear to document a vast need for legal services among low- and in some instances moderate-income populations. But they may not be an accurate measure of the 'effective demand' for lawyers in those communities, that is, how many of these problems poor people would take to lawyers if those services were free and readily available to them. Legal needs studies in nations where legal aid is a matter of right and fully funded reflect that far more poor people have justiciable problems than ask lawyers for their help each year, even though that help is plentiful and free. The continued existence of such a gap between 'legal needs' and 'effective demand' for legal assistance may be the result of (1) an irrational aversion to lawyers among some poor people, (2) a rational evaluation that their position lacks enough merit for a lawyer or anyone else to cure the problem, or (3) a feeling that some of the problems they have can be handled just as well by other services in the community – or a combination of these factors. Nevertheless, effective demand for lawyers remains substantial among low-income people in every country, while nations differ dramatically in their willingness to satisfy that demand.

An Overview of Access to Justice Strategies

The study of access to justice issues in modern societies begins with an appreciation of the essential role lawyers play in the regular civil courts in nearly every nation advanced enough to have a professional court system. To varying degrees, these societies place much of the burden on the competing parties in civil cases to investigate the facts, find the applicable law, and present the case to neutral, often passive decision-makers, whether professional judges or lay juries, or a mix. In many nations, those neutral decision-makers often are the only elements of the process the government supplies. Civil-law

countries on the European continent and elsewhere may use an 'inquisitorial system,' with judges guiding the discovery process and asking most of the questions at any hearings. Yet even then at least some responsibility for procuring the relevant factual evidence still often falls on the parties and requires the expertise and thus the expense of lawyers. Common-law countries such as Britain and its former colonies, and others using an 'adversarial system,' impose a much heavier burden on the competing parties, expecting them to find the relevant evidence, organize the presentation, and ask most of the questions at any evidentiary hearings and even locate and argue which legal principles should govern the resolution of the case. Depending on the division of responsibility between the government-funded courts and the private litigants, the latter can bear anything from a significant proportion to nearly all of the cost of the dispute resolution function as carried out in modern nations.

This article analyzes how modern nations seek to supply counsel to those unable to afford their own, and also how some nations have sought to restructure the dispute resolution function to reduce the need for lawyers. Three basic strategies are covered: first, providing government-funded lawyers to disputants who are unable to afford their own legal counsel (Section Increasing Access to Justice by Providing Government-Paid Lawyers); second, providing incentives to encourage private lawyers to represent people unable to afford to pay legal fees but without using government funds (Section Arrangements that Encourage or Require Private Attorneys to Represent Lower Income People without a Government Subsidy); and third, providing dispute resolution forums where disputants can participate fairly without the assistance of a lawyer (Section Increasing Access to Justice without Supplying Free Lawyers, Government Paid or Otherwise).

Increasing Access to Justice by Providing Government-Paid Lawyers

Empirical studies conducted in the USA support the hypothesis that litigants who lack lawyers are severely disadvantaged in the courts, at least as those courts still operate in the early years of the twenty-first century (Galanter, 1974; Sandefur, 2010; Greiner et al., 2013). Debtors sued in collection cases who were represented by counsel had a six times better chance of winning than those who defended themselves (Caplovitz, 1974). A megaanalysis examining scores of prior empirical studies on the impact of counsel in court proceedings found that representation by counsel increased the chances a party would prevail by anywhere from 17 to 1380% (Sandefur, 2010). Almost none of these studies used randomized assignment and thus are open to the possibility that the lawyers picked the more winnable cases. But a recent study employing this research strategy reported that tenants represented by lawyers still fared three times better than those who appeared in court without counsel (Greiner et al., 2013).

Most governments did not require empirical research to reach the conclusion that their lower income citizens required free counsel if they were to enjoy effective access to justice in the regular courts. During the second half of the twentieth century, nearly all industrial democracies began increasing their public investments in civil legal aid, thus increasing access to justice for their low-income citizens. But the level of commitment to equal justice for all citizens and the willingness to fund the lawyers necessary to that goal vary greatly from nation to nation. The World Justice Project's 'Rule of Law Index' ranked 124 nations on, among other things, 'access to civil justice.' Among the 23 'high-income' nations, the Netherlands ranked first on that scale, United Kingdom tenth, the United States twentieth, and Poland last (World Justice Project, 2011). This result may be explained in large part by the relative investments of these countries in civil legal aid as a percentage of their national gross domestic product (GDP) – the best measure of their comparative commitment to equal access to justice. As might be expected, no nation invested a substantial percentage of its GDP in civil legal aid. Nonetheless, by this measure, in 2012, Germany (a civil-law country) spent 2.5 times as much on civil legal aid as the US did, even though much less is expected of the parties and their lawyers in the inquisitorial process used in that country. Ireland and Hong Kong spent 3 times, Ontario (Canada) 4.6 times, Norway and Scotland 6.5 times, the Netherlands 8 times, and England and Wales 11 times more than the US did (Johnson, 2014; tables on pp. 920–921).

The economic downturn in Europe during recent years has prompted some of those nations to reduce their financial commitment to legal aid, along with other programs benefiting their low-income populations. The United Kingdom, for instance, is seeking to reduce its 2013–14 legal aid expenditures by 7.7% from the prior fiscal year (Legal Aid Agency, 2013–14). Yet this still would mean that nation would be spending more than 10 times as much of its GDP on civil legal aid as the US does.

The legal status of a citizen's right to counsel in the regular civil courts also varies greatly among nations and helps account for the 'access to justice' rankings on the 'Rule of Law' Index. While nearly all European and some Commonwealth nations have enacted a broad statutory right to counsel in civil as well as criminal cases, neither the federal nor any state government has done so in the USA. (In the US, the right to counsel currently is limited to criminal proceedings.) England first enacted a statutory right to counsel for poor litigants in civil cases in 1495, France did the same in 1852, Germany in 1877, the rest of Northern Europe in the late nineteenth or early twentieth century, Italy in 1923, Brazil in 1934, and several Canadian provinces and Commonwealth countries in the 1960s and early 1970s (Cappelletti et al., 1975; Johnson, 2000, 2010, 2014). In these countries, statutes guarantee low-income people that the government will supply them with a lawyer in any case where they qualify financially for such assistance, although they typically require the litigant's position to have some merit and the stakes to be significant (Johnson, 2010, 2014).

When most countries initially created a right to counsel they did not compensate the lawyers appointed to provide that representation but expected them to serve on a pro bono basis (Cappelletti et al., 1975). But over the course of the twentieth century more and more industrial democracies began to pay the lawyers serving poor people with government funds, until by the end of the century a majority of European nations and all of the Commonwealth countries chose to do so (Johnson, 2000). Italy, the only Western European democracy to rank

below the USA on the 'access to civil justice' scale on the 'Rule of Law' Index, is the only one on the list that still fails to pay the lawyers it assigns to fulfill the right to counsel (World Justice Project, 2011; Cappelletti et al., 1975; Johnson, 2014).

Europe and the USA also have taken different routes when considering whether to recognize a 'constitutional' or 'quasi-constitutional' right to counsel for indigent (poor) litigants. Despite interpreting nearly identical constitutional language, the U.S. Supreme Court and the European Court of Human Rights have reached opposite conclusions on the right to counsel in civil cases. In 1979, the European Court of Human Rights ruled that the 'fair hearing' guarantee found in the European Convention on Human Rights and Fundamental Freedoms required member governments to supply free counsel to indigent civil litigants in the regular courts (Airey v. Ireland, 1979). In a later decision, that court confirmed this right and extended the rationale to require that indigent litigants be given roughly 'equal arms' when contending with an opponent who has a lawyer (*Steel v. United Kingdom* 2005). In contrast, the U.S. Supreme Court has held the constitutional guarantee of 'due process' does not require the provision of free counsel to civil litigants, although it might in some cases (Lassiter v. North Carolina, 1981).

Some countries not bound by the European Convention have adopted the European, rather than the American approach, to this issue. For example, in 1937 the Swiss Supreme Court held that nation's constitutional guarantee that "All Swiss are equal before the law" required cantonal governments to provide free lawyers to those Swiss citizens who were too poor to hire their own in civil cases (*Judgment of 18 October 1937*; O'Brien, 1967). In 1999, the Canadian Supreme Court found the 'fair hearing' guarantee in that nation's new Charter of Fundamental Rights required governments to provide free counsel, at least in the type of case before the court, when authorities sought to retain custody of a parent's children (*New Brunswick v. G.J.* 1999). In 2001, the South African Land Reform Court held that indigent parties had a constitutional right to counsel in cases before that tribunal (*Nkuzi v. South Africa and the Legal Aid Board* 2001). Brazil has had a civil right to counsel provision in its national constitution since 1934, but only a few states comprehensively implement the right (Alves, ILAG Brazil 2005, 2007, 2009).

Lacking either a constitutional or statutory guarantee, poor people in many other countries around the world, including the USA, some Canadian provinces, and the Peoples Republic of China, receive legal assistance with their civil legal problems only if they can obtain help from a limited number of lawyers supplied through private or legislative charity (Zemans, 1979; ILAG China 2011, 2013, ILAG Canada 2013).

Nations also differ in how they deliver their government-subsidized legal services. There are three common models: compensated private counsel, salaried staff attorneys, and mixed systems. (These models are described in Johnson (2010) based on the authorities cited therein.) Under the compensated private counsel model, private lawyers represent lower income people just as they would paying clients. But when serving those low-income clients the lawyers submit their bills to the government rather than the client. The low-income clients, in turn, can usually choose any lawyer who has expressed a willingness to participate in the government program. This was the predominate delivery system in most of the largest nations of continental Europe, including the Commonwealth countries, when they first started providing public-funded legal services to the poor. This compensated private counsel model remains the sole approach in several of those nations, including France and Germany (Johnson, 2010, and sources cited therein).

Under the salaried staff model the government establishes separate legal aid offices, sometimes at the courts, but more often in 'clinics' or 'neighborhood law offices' in close proximity to concentrations of low-income people. The offices are staffed with salaried lawyers, usually employed full-time. When poor people have legal problems they bring them to one of these offices and are represented by a salaried lawyer. The USA, the People's Republic of China, South Africa, Ireland, a few Canadian provinces, and some Brazilian states, along with a few other jurisdictions, rely principally on salaried legal aid lawyers (Johnson, 2010; ILAG national reports cited therein.)

Several nations have moved to a mixed system that attempts to combine the virtues of the other two. Some of these mixed systems, such as the one in Quebec, Canada, adopt a 'client option' approach, allowing clients to choose between salaried staff lawyers and compensated private attorneys to represent them in a given case. Others, such as in Ontario, Canada, divide legal problems between the two systems on a 'subject matter' basis – typically with clients required to take all 'poverty law' cases (e.g., housing, consumer, government benefits, etc.) to salaried attorney offices and the more traditional legal problems such as divorce to compensated private counsel. Still others have developed a 'functional' divide between salaried staff and compensated private counsel. In the Netherlands, salaried lawyers and supervised paraprofessionals handle all preliminary legal advice and short-term legal assistance, but private lawyers provide all the representation in litigated cases. Finland follows that same pattern, except it offers clients involved in litigation the choice between salaried lawyers or compensated private lawyers (Johnson, 2010).

Some countries using the compensated private counsel model have experienced ever-expanding legal aid budgets, often caused by higher legal fees. These budgetary considerations have led some governments, most notably in England, to begin exploring modifications calculated to reduce costs. One such approach is 'franchising,' where the government signs contracts with certain private lawyers and law firms to provide services at reduced fees; another is 'capitation,' where lawyers agree to handle all the legal problems generated by the entire low-income population in a defined geographic area for a fixed per capita sum (ILAG England 2007, 2009; Moorhead, 1998).

Arrangements that Encourage or Require Private Attorneys to Represent Lower Income People without a Government Subsidy

In some nations, government-subsidized lawyers coexist with fee arrangements that encourage private attorneys to represent lower income clients without government funding in certain categories of cases. The most common of these incentive arrangements are the following: (1) contingent fees (Section Contingent Fees), (2) conditional fees (Section Conditional

Fees), and (3) court-awarded fees, usually in cases that further some important government policy (Section Court-Awarded Fees). In addition to these economic incentives, in many countries public policies encourage or require private lawyers to devote some of their time to the representation of poor people on a pro bono (uncompensated) basis (Section Voluntary and Mandatory Pro Bono Legal Services).

Contingent Fees

The USA is almost unique in allowing lawyers to represent clients on a 'contingent fee' basis. Under fee contracts allowing them a percentage (typically 33–40%, but sometimes lower for early settlements and higher for trials) of the client's recovery, lawyers agree to assume the risk of failure, not charging any fee if they lose. Thousands of the poorest citizens are represented each year in cases where they are suing for a substantial sum of money and have a good chance of winning. At the same time, the contingent fee system offers no help to low-income people who are defendants, or who are plaintiffs in the many categories of legal disputes that do not involve monetary stakes or where the potential financial recovery is too modest to cover the risk of loss (Regan et al., 1999).

The contingent fee system is not without its critics. Some contend that the fee percentages are too generous to lawyers, leaving their clients with less than full compensation for their injuries. Others, however, respond that without the bonus of substantial fees when they win, contingent fee lawyers could not afford to take riskier or smaller cases and thus would contribute less to increasing access for the low-income population (Regan et al., 1999). Some jurisdictions have legislated 'caps' on injured parties' damage recoveries and on the percentages of those recoveries lawyers can earn – at least in certain types of cases (Regan et al., 1999). Typical are caps on recoveries and legal fees in medical malpractice cases, which can make it difficult for poor people to find lawyers unless they suffer a catastrophic injury (California Medical Injury Compensation Reform Act).

Conditional Fees

Most countries, other than the USA, use a 'loser pays' rule in allocating legal fees. That is, losing litigants not only pay their own lawyers but also remit at least a 'reasonable fee' to the winners' lawyers. A few nations have altered this rule in a way that may allow lawyers to serve low-income clients without a government subsidy in a variety of cases.

In 1995, the United Kingdom introduced a modified form of the 'conditional fee' model, one that applies to nearly all civil litigation involving monetary stakes no matter the economic means of the parties. Under this model lawyers do not charge their clients a fee if they lose, just as is true in the 'contingent fee' system. But lawyers who win can charge an 'uplift' (usually called a 'success fee') of up to 100%, in effect doubling their fee. Until 2013, the losing litigant had to pay this 'success fee' as well as the regular fee, to the winner. But as a result of a change enacted that year, the 'success fee' is paid out of the clients' monetary recovery. However, the total amount of the winning lawyers' fee (including the 'success fee') cannot exceed 25% of that recovery after deducting any provisions for future ongoing care or future lost income. Should they lose, clients are not relieved of their obligation to pay the other side's fees. But, if they can afford it, they can purchase insurance to cover this risk (Ministry of Justice, 2013).

The U.K. government expects the 'conditional fee' system to supplant legal aid for the claimant's side of most cases offering the prospect of a monetary recovery. Critics point out the prospects of success must be unusually favorable before lawyers will be willing to provide representation under a 'conditional fee' system. They will not receive a fee from either side if they lose and the 'reasonable fee' they receive as an 'uplift' from their clients' recoveries will be far less generous than the 33–50% of the judgment that contingent fee lawyers typically earn when they win (Moorhead, 2000).

Court-Awarded Fees

Most jurisdictions in the USA depart from the general 'American' rule which expects all litigants, winners, and losers to bear their own legal fees and costs (Luebsdorf, 1984) and instead shift fees to the losing party in certain categories of cases in order to increase access to justice in those cases. These are

1. Statutory fee-shifting – in lawsuits under statutes specifically authorizing fee-shifting in favor of private parties whose cases enforce the public policies embodied in those statutes.
2. Public interest fee-shifting – in lawsuits where the court, rather than the legislature, determines that the public interest will be promoted by awarding winning litigants the bonus of requiring the loser to pay their legal fees.

Both statutory fee-shifting and public interest fee-shifting offer an alternative source of funding for those unable to afford their own counsel. They are especially important in major litigation not offering the possibility of a substantial monetary recovery, such as those ordering the government or some other institutional defendant to change its policies or practices in the future. The court is typically not limited by the size of the winning party's economic recovery, which often is nothing, but can award winning lawyers their regular full hourly fees for the time they spent on the case – at least if the request is for a 'reasonable' amount of time and an appropriate hourly fee in the local community (Murr, 2000). Beyond that, in some jurisdictions, lawyers can apply a 'multiplier,' often doubling or tripling the lawyers' fee in order to recognize the riskiness, complexity, or significance of a particular piece of litigation (Klaber, 2006).

Voluntary and Mandatory Pro Bono Legal Services

As mentioned earlier, most European countries originally implemented the statutory right to counsel by appointing lawyers to provide free legal representation to poor people without compensation – a form of *mandatory* pro bono services. During the twentieth century most of these nations found this approach unsatisfactory and shifted to a system that compensated the lawyers representing the poor (Cappelletti et al., 1975; Huls, 1994; Johnsen, 1994), although a few, like Italy, still depend on drafting lawyers to provide legal aid (Cappelletti et al., 1975).

Voluntary pro bono services depend entirely on the charitable impulses of the private legal profession. Faced with a shortage of government-funded legal aid the USA in the last decades of the twentieth century and the first decade of the twenty-first century, legal aid supporters have attempted to encourage more private lawyers to volunteer time to represent the poor. In many states and cities, organized pro bono programs have been established. Some require private lawyers to report annually on the hours devoted to pro bono services (see, e.g., Florida Bar Association, 2014). A national program issued a 'pro bono challenge' to the 500 largest law firms, asking them to commit 3–5% of the firm's billable hours to pro bono representation of the poor. As of 2012, this effort had succeeded in signing up over 100 firms, and corporate law firms donated over two-and-a half-million hours of legal services to the low-income population that year (AmLaw Pro Bono Report, 2012). Some other nations – Sweden and Australia, among them – also have begun to look to pro bono services to fill some of the gaps created by reductions in government legal aid budgets (Regan et al., 1999).

There is a serious question, however, whether societies can expect pro bono legal services to play more than a limited, supplementary role in the delivery of legal representation to low-income people. It seems there is no more reason to expect lawyers to donate enough services on a pro bono basis to meet the low-income population's total need for legal services than to expect medical doctors and hospitals to supply enough of their services pro bono to replace the present government-funded health care systems for the poor – e.g., Medicare and Medicaid in the USA, the National Health Service in the UK, etc.

Increasing Access to Justice without Supplying Free Lawyers, Government Paid, or Otherwise

Professional lawyers appear essential to fair proceedings in the regular courts of most modern countries, as the European Court on Human Rights held in Airey v. Ireland (discussed in Section Increasing Access to Justice by Providing Government-Paid Lawyers). The legal rules governing the decisions are complex, the procedures intricate, and investigatory techniques difficult to master. For all these reasons, unrepresented parties seldom have a chance for a 'fair hearing' in the regular courts – especially if the opposing party has a lawyer.

Yet the European Court of Human Rights also recognized it may be possible for governments to create forums – for some cases at least – where the assistance of lawyers is not crucial and thus effective access to justice can be achieved without providing free counsel to lower income disputants (Airey v. Ireland, 1979). It is possible to identify five approaches that various countries have tried, alone or in combination, in an attempt to deprofessionalize dispute resolution: (1) simplification of procedures (or diversion to simpler forums) (Section Redesigned Forums – Simplification of Procedures and/or Redistribution of Functions and Responsibilities); (2) simplification of the substantive law (Section Simplification of Substantive Legal Rules Governing Disputes); (3) the use of less expensive, nonlawyer advocates (Section Use of Less Expensive, Nonlawyer Representatives), (4) out-of-court assistance to prepare disputants to represent themselves (Section Out-of-Court Assistance to Unrepresented Litigants), and (5) technological substitutes for legal expertise (Section Technological Substitutes for Legal Expertise).

Redesigned Forums – Simplification of Procedures and/or Redistribution of Functions and Responsibilities

For simpler disputes it might be feasible to construct simpler dispute resolution processes, and for any dispute it might be possible to shift most of the responsibility for discovering and presenting the facts from the private parties to the judges or others the government pays to operate the forum. But there are competing values as well as questions about the efficacy of these approaches that have not yet been resolved through empirical study or extensive experience.

Many complex procedures have been created not to enrich the legal profession by making lawyers essential to operate the system but for the purpose of allowing the courts or other forums to function in an efficient and timely way, and to produce accurate and just results. For instance, typically the parties must go through several proceedings before reaching a full-blown trial in order to weed out meritless claims and defenses as soon as possible. Another set of procedural rules limits the forms of evidence parties may introduce in order to ensure disputes are decided on the basis of reason and not emotion and prejudice. But if that procedural complexity is important if not essential to the efficiency of the courts and the validity of their decisions, when if ever is it desirable to strip away that complexity and thus presumably make the system more accessible to unrepresented parties?

There are categories of cases that seem possible candidates for a simplified process – in essence where all the usual steps can be collapsed into a single court appearance. During that session, the judge can hear and evaluate the evidence from both sides and render a decision, without worrying whether the case could have been resolved earlier and with less expenditure of judicial time. But this brand of one-shot consolidated proceeding appears practical only for relatively simple cases, where there is little advantage in weeding out weaker cases without a full hearing at earlier stages in the process.

Early in the twentieth century, several countries started 'small claims courts' to hear disputes involving minor stakes. Using simple procedures and expecting the judges to take a more active role in developing the facts, these courts were designed to function well without lawyers (Turner and McGee, 2000). Some criticize small claims courts for pitting unrepresented individual litigants against lawyers hired by institutions such as credit companies, landlords, and businesses (see, e.g., Elwell et al., 1990; Sterling et al., 1990). A few jurisdictions, such as California, responded by banning lawyers entirely from these courts. This did not always succeed in leveling the playing field in those courts, however, as institutional litigants began deploying well-educated nonlawyer employees to specialize in handling their cases in the small claims courtrooms (Moulton, 1969). Overall, studies of small claims courts have arrived at mixed findings about their fairness to individual litigants, especially in cases involving institutional opponents who were

represented by lawyers or nonlawyer advocates (Yngvesson and Hennessey, 1975).

Some jurisdictions also have created specialized forums roughly analogous to the small claims court model to handle certain narrow categories of cases (housing courts, labor courts, social welfare courts, and the like) with the expectation that their simplified processes would allow many disputants to represent themselves. Once again, the results are mixed (Cappelletti et al., 1978–79).

In addition to simplified courts within the court system itself, some jurisdictions have created administrative bodies empowered to resolve certain categories of disputes. For example, in the United Kingdom, 'tribunals' composed of part-time volunteers have been used to decide disputes arising out of public housing and other government benefit programs (Cappelletti et al., 1978–79). In some Canadian provinces, an agency called the 'Office of the Rentalsman' was set up to resolve most landlord–tenant disputes (Rentalsman). In many jurisdictions administrative hearings decide whether a worker is entitled to compensation for job-related injuries or whether a discharged employee will receive unemployment compensation. Once again, the procedures are designed to be simple compared to the regular courts and typically disputants are encouraged to appear without lawyers. A recent study of one such unemployment compensation hearing system reported that unrepresented employees fared as well as those who were represented by supervised Harvard law students (Greiner et al., 2012).

In recent years, private mediation and arbitration (often called Alternative Dispute Resolution) have emerged as major alternatives to the regular civil courts, especially in the USA. The primary motive behind the growth of these alternative forums, however, arises not from a desire to increase access to justice for lower income individuals, but to help more affluent parties, especially businesses, reduce cost, delay, and the risk of large damage awards (Abel, 1982; Johnson, 1993). While private mediation and arbitration have not proved a significant strategy for increasing access to justice when the disputes pit individuals against institutions, they have offered a useful alternative to litigation in disputes between evenly matched individuals (Menkel-Meadow, 1999).

Simplification of Substantive Legal Rules Governing Disputes

One of the major reasons people must employ lawyers to represent them is the complexity of the legal rules the judge or jury will apply to decide who wins. Some suggest we can reduce the need for lawyers and thus improve access for lower income disputants by simplifying those rules. What is called 'simplifying the law' seems to embrace three quite different meanings of the term.

For many, it merely means expressing the legal rules in 'plain language' that is, converting multisyllable technical legal terms into language understandable to people with a secondary or sometimes elementary school education. To the extent this can be done, this form of law simplification would seem to be helpful to unrepresented litigants. But many legal rules are based on concepts that remain complex and difficult to fully comprehend even when expressed in plain language. Furthermore, complexity also often arises because of the sheer number of rules that may interact to determine the proper resolution of a given dispute – the several elements of each possible cause of action, the several elements of each possible defense, and the like. No matter how simple the language and even the concepts that may be involved, it often takes expertise to work through the maze of rules. For these reasons, simplifying the language of law has its limits as a way of increasing access for unrepresented litigants.

A second form of law simplification reduces the number of rules that determine the outcome of a given class of cases. An example of this is the substitution of 'no-fault' divorce for a 'fault-based' system under which those wanting to terminate their marriage had to satisfy one or the other of several alternative grounds – cruelty, desertion, adultery, etc. In some jurisdictions, legislatures not only enacted no-fault divorce laws but authorized couples to obtain 'summary divorces' if they had no children, limited property, and short-term marriages (see, e.g., California Family Code). Japan has long had a system of 'mutual consent divorce,' where parties who have agreed to divorce and settled the terms of the divorce can merely register that event at the same government office where they obtained their marriage license, a process that accounts for about 90% of divorces in that country (Yokochi, 2009). In an ever more complex society, however, it is questionable whether there will be that many opportunities to reduce the number of legal elements required to decide cases – especially because most of the complexity is the product of interest groups and their advocacy for new laws or new interpretations of old laws they deem favorable to them.

Third, law simplification can mean the substitution of a single generalized standard in place of a sequence of precise rules the judge is expected to apply in deciding certain disputes. This grants the judge broad discretion in reaching what he or she perceives to be the correct resolution – to do justice as he or she sees it. It also means unrepresented parties do not have to attempt the daunting task of mastering a whole set of detailed legal standards that will determine the outcome of their disputes, lessening the disadvantage when contending with parties who have lawyers (Zorza, 2014). The potential downside of reliance on a general standard is its subjective nature. It offers no check on any biases the judge may harbor in favor or against certain parties or for a personally preferred outcome, making the process closer to a system 'of men, not laws.'

Use of Less Expensive, Nonlawyer Representatives

Some specialized lower cost forums permit nonlawyers to represent parties appearing before them. Some even rely exclusively on nonlawyer advocates for this role. Presumably the use of these less-educated and less-expensive personnel enhances access by lowering the cost of representation to the parties or to the government employing the advocates. A 1998 study in the United States evaluated the difference between representation by lawyers and representation by lay advocates in certain administrative forums, and found only marginal differences in the quality of representation or the results achieved (Kritzer, 1998b). Unresolved, however, is whether those findings would hold up in the regular courts that decide a broader range of disputes or where one litigant was

represented by a lawyer and the other a lay advocate. Another issue is whether nonlawyer advocates are necessarily less expensive than lawyers and thus their use can increase access to justice. The United Kingdom allows nonlawyers to represent litigants in certain of its tribunals. However, it is unlikely this lowers the cost and thus enhances access to justice because the fees are a percentage of the recovery and remain the same irrespective of whether the claimant's representative is a lawyer or a nonlawyer (Ministry of Justice, 2013).

Out-of-Court Assistance to Unrepresented Litigants

Several countries, especially those with only limited lawyer resources committed to legal aid, have seen unrepresented litigants engulf their courts. Some U.S. jurisdictions report 70–80% of litigants in family law court appearing without counsel, and as many as 90% of tenants are unrepresented in eviction cases while 90% of landlords are (Engler, 2010). Prompted as much by the judges as by advocates for the poor, and unwilling or unable to provide lawyers to the overwhelming numbers appearing in their courts, many of those jurisdictions have begun providing comparatively low-cost services designed to help those litigants prepare and present their own cases.

This assistance can take several forms, sometimes more than one available in a single jurisdiction. In some places, unrepresented litigants are offered classes that teach the participants how to draft pleadings and file them in court, along with an explanation of what they can expect when they appear in court and how litigants are expected to behave in those forums. At a more individualized level of assistance, what are often called 'self-help' centers offer one-on-one guidance from lawyers or, more frequently, supervised paralegals. At these centers, often located in courthouses, staff members help litigants fill out the pleadings or paperwork the courts require and show them how to conduct themselves in presenting their particular case to the judge. Some show videos to help litigants visualize what it will be like when they interact with a judicial officer. None of these centers, of course, provide representation in the courtroom – it is purely pretrial assistance they offer (Zorza, 2002).

Interviews and anecdotal evidence suggest judges find litigants who have received self-help assistance present the court with more coherent pleadings and other written documents and are somewhat better prepared to present their cases. In that sense, these services make the judge's job easier (Henschen, 2002; Graecen, 2002). Self-help assistance also usually is adequate – as well as far less expensive – in uncontested cases such as mutual consent divorces with no disputes over property, child custody, etc., and where the only task is properly preparing paperwork and navigating the process to an agreed-upon conclusion (Cavanaugh, et al., 1976). What is less clear is whether self-help assistance is sufficient to increase substantially the litigant's ability to win contested cases – with one study showing litigants receiving self-help assistance faring no better than those lacking that help (Steinberg, 2011) and another finding those represented by lawyers were three times more likely to win than those limited to out-of-court assistance (Greiner et al., 2013).

Even the most committed advocates for self-help assistance recognize unrepresented litigants – with or without pretrial assistance – find it difficult if not impossible to succeed in the extreme adversarial world typical of common law courts. Thus, these advocates have urged judges to relax the adversarial model when unrepresented litigants are involved in the proceedings and to assume more responsibility for eliciting the evidence needed to decide the issues in the case (Albrecht et al., 2003; Zorza, 2002). In response, some jurisdictions have enacted rules expressly authorizing judges to give assistance to unrepresented litigants and to assume a more inquisitorial role in such cases (California Judicial Council, 2007). Whether most judges will be willing to shift to that inquisitorial model and whether judicial budgets will allow them the time to do so remains a critical unresolved issue (Johnson, 2014).

Technological Substitutes for Legal Expertise

Several technologies have been deployed to give some level of legal assistance to low- and moderate-income people – often similar to the classes or the individualized help otherwise provided in person at self-help centers as described in the previous Section Out-of-Court Assistance to Unrepresented Litigants.

Many court systems or legal services programs in the United States have developed Web sites filled with forms, plain language explanations of the law, information about how to represent oneself in court, and other relevant information, often including video clips illustrating what to do and how to do it (Staudt, 2005).

Nearly every state now has at least one telephone hotline providing legal information to callers, many of which provide one-on-one advice and limited assistance as well as referrals for further legal help (Houseman, 2005).

In a more sophisticated form of technological support, some court systems and legal services providers have developed interactive computer programs that help the litigants produce appropriate pleadings to submit to court. Sitting down at a kiosk or a computer linked to the Web, an unrepresented litigant responds to a series of questions appearing on the screen. Once those questions have been answered, the kiosk or a printer attached to the computer the litigant is using spews out the relevant court documents and instructions about where and how to file them. That way the language of the street is turned into the language of the law. Typically, users also can click on videos that orient them to the tasks ahead when they take their cases to court (iCAN! Legal; Staudt, 2005).

There is survey evidence suggesting courts find the resulting documents a substantial improvement over what these litigants prepare on their own (Greasen, 2002). But as of yet there has been no assessment of outcomes to determine whether and how much these computer-generated litigation documents help litigants to prevail in court if they lack legal representation when they appear before the judge.

The Beginnings of Comprehensive Fully Integrated Systems Seeking to Provide Cost-Effective Justice to Low- and Moderate-Income People

The Netherlands appears to be leading the way in its efforts to integrate technology, nonlawyer legal services, self-help

assistance, and full representation into a comprehensive system for giving lower income people access to justice in the most cost-effective way. It has recently introduced a sophisticated interactive Web site called the Rechtwijzer (Roadmap to Justice). This Web site uses a series of questions based on a decision tree that encourages and seeks to allow prospective litigants to analyze and solve common legal problems – family, housing, consumer, etc. – on their own. Yet when users reach an impasse the site refers them to outside experts and organizations (Legal Aid Board). This same Web site includes a still more sophisticated interactive program for 'divorce and parenting' issues available at rechtscheidingsplan.nl (Legal Aid Board, Rechtwijzer 2.0, www.openlab.com/2014/01/16rechtwijzer-justice-platform). It guides the parties through the entire process – from the decision whether to divorce through the issues, such as child custody and support that must be confronted and resolved. Along the way the program encourages the parties to settle their differences through online negotiation or online mediation rather than moving ahead with litigation (Legal Aid Board; New Law Journal, 18 April 2013).

When the Rechtwijzer Web site proves insufficient or not attractive to citizens, they turn to the next layer of assistance – 'law counters' that provide in person advice and short-term assistance. These 'law counters' are staffed by lawyers and supervised paralegals and their services are not means-tested. When advice and short-term assistance are not enough to solve the problem or where the users have already been sued, those who are financially eligible are referred to private lawyers compensated by the government who will provide them the necessary service including representation in court (ILAG Netherlands National Report, 2011, 2013).

Technology, computer technology in particular, may have only begun to transform the dispute resolution process in ways that could improve access for lower income litigants. Video technology combined with smart phones, laptops, and tablets may make it possible to avoid long trips to courthouses and costly days off in order to hold court hearings and resolve disputes. Voice-recognition software combined with translation software may soon enable people who do not speak the language of the court or other forum to communicate easily with those serving on that court or forum. The words the litigants speak in their language will be heard by the decision-makers in theirs, and vice versa. Moreover, advanced artificial intelligence could lower the cost of litigation by quickly analyzing the law and the facts of a dispute and producing a suggested decision.

Future Issues in the Movement toward Equal Access to Justice

The major issues for government-funded legal aid and equal access to justice in the twenty-first century include (1) whether a 'globalization of constitutional values' will lead all nations to recognize a constitutional right to equal justice (and to counsel when needed) in civil cases; (2) whether those nations that already have such a right will develop delivery mechanisms and other dispute resolution reforms allowing them to guarantee effective access for lower income citizens at politically sustainable levels of public investment; (3) whether the vital importance of equal access to justice for democratic government and political stability will cause developing countries and former communist nations to institute significant legal aid programs; and (4) whether alternatives to counsel – nonlawyer advocates, simplified procedures and substantive law, self-help assistance, technology, and inquisitorial judges – will be able to afford low-income disputants fair and equal justice at less cost and in which circumstances that will be possible. As it has in the past, social science will have much to contribute not only to the design of these initiatives, but more importantly to their evaluation. The insistence on empirical proof will offer the most effective guarantee that what emerges indeed grants every citizen, irrespective of means, the right to equal justice that democratic societies promise to all.

Justice and Health

Johannes Siegrist, Heinrich-Heine-University of Duesseldorf, Duesseldorf, Germany

Abstract

This contribution explores adverse effects of experienced injustice on health. At the macrosocial level, income inequality is one such source of experienced injustice, which is associated with population health in epidemiological studies. At the mesosocial level, perceived unfairness in organizations (organizational injustice) has been associated with poor health of employees. Similarly, violations of the principle of justice of exchange at work elicit stress reactions with adverse long-term effects on health, as documented by research based on the effort–reward imbalance model. Unjust social exchange is an important psychosocial determinant of health.

Background

The association of justice with health is commonly interpreted in the frame of unequal access to health care. In fact, being deprived from health care provision in the presence of an urgent health problem violates a basic human right. In order to tackle this basic injustice all health care systems have developed procedures, which, to different extents, regulate people's access to health care. Yet, given the universal dilemma between demand and supply, inequalities in the provision of health care are widespread in a majority of health care systems worldwide. A vast literature in the fields of health economics, medical ethics, and medical sociology deals with core questions of injustice in this context (*see* Socioeconomic Status and Health Care).

The topic of this contribution differs from this main line of reasoning. Here, we address the question whether the experience of injustice has an impact on human health and well-being and, if so, what mechanisms are responsible for this association. How can we define and measure experienced injustice and what is the empirical evidence for its association with health? In other words, we maintain that experienced injustice acts as a distinct psychosocial stressor that generates strong negative emotions and is associated with psychobiological stress responses with adverse long-term consequences on health.

In most instances, injustice cannot be observed directly. Apart from the extreme situation where injustice manifests itself as direct physical violence there is a broad spectrum of conflicting social interactions or violations of social norms, which evoke experiences of injustice. It is crucially important to identify those socioenvironmental constellations that trigger experiences of injustice. Yet, it is equally important to assess the subjective appraisals of persons exposed to these encounters as these appraisals affect the individual consequences.

Against this background different notions of 'justice' are mentioned, and a leading psychological theory of perceived justice is described. In the following sections three main scientific approaches toward studying health effects of perceived justice or injustice and their main findings are summarized, dealing with income inequality, organizational injustice, and injustice of exchange at work.

Notions of Justice

Justice is a broad concept composed of different dimensions. One dimension addresses the preferences and behaviors of individuals who are prepared to respect others, to treat them fairly, and not to harm them. In this sense, being just is an individual attribute or disposition. Another dimension of justice concerns its corrective function, the criminal law. It regulates the compensation of all types of criminal offense by applying sanctions and punishments. Procedural justice is a third dimension. Here, the process of how established rules are observed and how decisions are reached matters most. Core aspects include the equality of opportunity, the transparency of information, the avoidance of biased judgments, and the justification of decisions. Nevertheless, in everyday life, two further dimensions of justice are particularly important, distributive justice and justice of exchange. These notions relate to all types of social cooperation and conflict between people. Distributive justice deals with the principles of how scarce and desired resources are distributed among individuals, whereas the principle of justice of exchange maintains that benefits received from a partner should be reciprocated by equitable returns. Some form of inequality is inherent in many cases of distributive justice, while equity is the leading principle of justice of exchange.

There are several other notions of justice (e.g., interpersonal, informational, intergenerational, environmental justice), but distributive justice and justice of exchange have eminent significance for human health because they mainly concern the things 'worth driving for' in social life, such as appreciation, love, trust, material rewards, security, control, engagement, and belonging.

Substantial progress in analyzing the psychological processes generating experiences of injustice was achieved by J.S. Adams (1965). In his equity theory he maintained that a person (A)'s costs invested in an activity that is useful for another person (B) are expected to be compensated by comparable investment from that person (B) toward person (A). The perception of justice or injustice is contingent (1) on the notion of balance between 'cost' (transferred from A to B) and 'gain' (transferred from B to A), and (2) on the fit of this balance or ratio with a comparable balance or ratio of 'cost' and 'gain' experienced by a reference person (C) or a reference

group. Reference persons or a reference group are usually defined by horizontal comparison, where persons living in similar socioeconomic or sociocultural circumstances are chosen as a standard of evaluation. According to Adams, two types of perceived distributive injustice are to be distinguished, overfitting and underfitting. In the first case, the ratio of 'gain' relative to 'cost' in person (A) is higher than the corresponding ratio in reference person (C). A feeling of unease due to unjustified advantage may result from this experience. In case of underfitting, the ratio of 'gain' relative to 'cost' in person (A) is lower than the corresponding ratio in reference person (C), giving rise to negative emotions of anger and irritation. Equity theory posits that both states of injustice trigger some kind of inequity aversion that motivates people to reduce these discrepancies by behavioral or cognitive changes with regard to their 'costs' or 'gains.' A stronger motivation of change is expected in case of underfitting as compared to overfitting, given the powerful impact of loss experience.

In Adams' concept, 'inequity distress' was introduced as a hypothetical construct which was not measured in empirical tests of the theory, but which was useful in explaining subsequent behavioral or cognitive changes (Greenberg, 2010). Adams' main interest was to understand adaptive behavioral changes following perceived inequity rather than to explain individual health effects. This latter interest received primary importance in the frame of a more recent development, the effort–reward imbalance model that, in part, builds on Adams' equity theory (see Section Health Effects of Injustice: The Model of Effort–Reward Imbalance).

The following sections summarize core findings of three main scientific approaches toward studying health effects of perceived justice or injustice. The first approach represents a macrosocial perspective where inequity refers to the distribution of income across society. In the second approach, the concept of organizational justice developed in organizational psychology and management sciences is applied to epidemiological studies testing associations of organizational procedures with employees' health. In the third approach, injustice of exchange is analyzed in the frame of employment conditions where efforts spent by working people are not reciprocated by appropriate rewards. Adverse health effects are examined with reference to psychobiological stress models.

Health Effects of Injustice: Income Inequality

One of the most robust findings of social epidemiology documents a social gradient of morbidity and mortality in modern societies: the lower peoples' positions in the social hierarchy, the worse their health (Marmot and Wilkinson, 2006). Income is an important determinant of socioeconomic position, demonstrating strong effects on health and life expectancy (*see* Socioeconomic Status and Health). However, if correlations of household income with mortality, or correlations of gross national product with life expectancy, are compared across countries this correlation almost disappears in countries with the highest income levels. Here, it appears that the distribution of income influences average life expectancy of a society more so than the absolute level (Kawachi, 2000). In countries with a high degree of income inequality population health seems to be worse than in countries with a more egalitarian distribution. While high income inequality is interpreted as a condition amenable to experiences of distributive injustice, several questions need to be answered: Is the correlation of income inequality with population health restricted to cross-country comparisons, or does it equally exist within countries? Does the correlation persist after taking major confounding factors into account? And how can these associations be explained?

There are several ways of measuring the distribution of income (Kawachi, 2000). Among these, the Gini coefficient is most often used and best known. It theoretically ranges from 0.0 (perfect equality) to 1.0 (perfect inequality). In a majority of cross-national studies strong correlations between national Gini coefficient and mortality rate (e.g., age-specific, all-cause mortality) were observed. However, given a restricted comparability of respective data, a more convincing test may result from within-country analyses. Several such analyses are now available. They confirm the reported association, most impressively for the USA, where income inequality and poverty together accounted for about one-fourth of the state variations in total mortality (Kawachi, 2000).

When interpreting these associations one should notice that they represent ecological correlations, thus being subject to ecological fallacy. An association observed at the level of aggregate data cannot readily be translated to the level of individual data. Several confounding factors (e.g., individual household income, household size, education) have to be taken into account in order to disentangle compositional effects (e.g., a high proportion of poor people with elevated mortality risks living in areas with high income inequality) from contextual effects (the direct impact of income inequality in a certain area on individual health of its inhabitants). Although methodological concerns still prevail in this research there is some evidence of contextual effects of wide income distribution on poor population health (Wilkinson and Pickett, 2011). Therefore, it is important to know how this type of distributive injustice may affect health.

One explanation maintains that societies with a high level of income inequality are less likely to invest into public goods and services, thus weakening the quality of infrastructure and the social capital or social cohesion among residents of respective areas. Material and psychosocial adversity in turn may exert negative effects on population health. Another explanation focuses on negative emotions and stress reactions following exposure to relative deprivation. High income inequality evokes feelings of being treated unfairly and socially excluded among those who are at a clear distance from the top. Perceived distributive injustice is associated with frustrated expectations, feelings of inferiority, disrespect, and even shame experiences with adverse effects on health (Wilkinson and Pickett, 2011). Although plausible these associations have not yet been examined with convincing experimental and epidemiological evidence (see Section Health Effects of Injustice: The Model of Effort–Reward Imbalance). Therefore, more research on the association of income inequality with population health is needed, given the high sociopolitical and economic importance of this topic.

Health Effects of Injustice: The Concept of Organizational Justice

Whereas research on income inequality addresses the macrosocial level the concept of organizational justice relates to the mesosocial level of institutions and organizations. The notion of organizational justice was elaborated in organizational psychology and management sciences several decades ago, and was applied to health research only a couple of years ago in the frame of investigating psychosocial determinants of work-related disorders in epidemiological cohort studies (Elovainio et al., 2002). Three dimensions are distinguished in this concept: distributive justice, the perceived fairness of an organization's distribution of relevant resources; procedural justice, the perceived fairness of observing rules and applying agreed-upon standards in decision making; and interactional justice, the perceived fairness of interaction and communication in organizations, in particular between managers and employees (e.g., being treated with respect; relational justice; being informed in an accurate and timely way (informational justice) (Adams, 1965; Greenberg, 2010)).

It is obvious that each dimension contributes to a positive climate in organizations, strengthening job performance, and organizational commitment among employees. What is the evidence that perceived justice in organizations is associated with mental or physical health? To answer this question different scales measuring perceived justice were applied in epidemiological studies. As the most frequently used instrument focuses on procedural and interactional justice (Moorman, 1991), fewer results are available so far on the effects of distributive justice on health (see Section Health Effects of Injustice: The Model of Effort–Reward Imbalance). In a recent review on mental health, it was concluded that 10 prospective studies found higher mental health risks among employees reporting poor relational justice, with increases in the outcome measures ranging from 1.2 to 1.6. Similarly, low procedural justice was associated with higher risk of future depressive symptoms and medically certified depression in six prospective studies, with relative effects ranging from 1.4 to 1.9 (Ndjaboué et al., 2012). Additional findings confirmed elevated risks of sickness absence and of coronary heart disease in association with low organizational justice (Kivimäki et al., 2005; Greenberg, 2010).

In conclusion, epidemiological evidence points to a robust association of some aspects of perceived organizational injustice with poorer mental health. Additional health risks were also explored in a few studies, but the pathways linking organizational injustice with health outcomes are still poorly understood. At the level of worksite health promotion programs these results support investments in leadership training and improved interactional skills in organizations.

Health Effects of Injustice: The Model of Effort–Reward Imbalance

'Effort–reward imbalance' was proposed as a stress-theoretical model of a health-adverse psychosocial work environment that is based on the notion of justice of exchange (Siegrist, 1996). Social reciprocity, a fundamental principle of transactions that are characterized by some form of utility, lies at the core of the work contract, which defines distinct obligations in exchange for rewards (money, appreciation, career opportunities (promotion, job security)). The model asserts that failed reciprocity, in terms of high effort and low reward, generates strong negative emotions and associated stress reactions with adverse long-term health consequences. Failed reciprocity occurs frequently if the workers have no alternative choice in the labor market or if they are exposed to highly competitive jobs. Moreover, people with excessive work-related motivations and attitudes are at risk of experiencing this imbalance. Although there is conceptual overlap with the analysis of distributive justice in equity theory (Adams, 1965), the model has its original focus in sociological role theory, specifically the work role, emphasizing stressful effects of threats to social status and related rewards. In addition, the model combines extrinsic (situational) and intrinsic (personal) conditions of continued (chronic) imbalance, and it provides a new explanation of the occurrence of stress-related disorders by linking the experience of failed reciprocity in core social roles to the brain reward system and related psychobiological processes (Siegrist, 2005). The model also differs from the concept of organizational justice as it is applied to social exchange beyond work-related organizational contexts; in addition it explicitly deals with interpersonal comparisons beyond the relevant 'give' and 'take' relationship.

Effort–reward imbalance at work, as measured by a standardized, psychometrically validated questionnaire (Siegrist et al., 2004), was shown to be associated with significantly elevated risks for several chronic conditions in epidemiological studies, in particular depression (Rugulies et al., 2013) and coronary heart disease, including some of its main risk factors (Greenberg, 2010; Steptoe and Kivimäki, 2012; Xu et al., 2009). Importantly, these findings result from studies in different regions of the world, thus pointing to a rather basic type of stressful human experience. This latter notion is supported by evidence demonstrating associations of failed reciprocity in other social roles (e.g., volunteering, caring, homework, close social relationships) with several health indicators (Chandola et al., 2007) (*see* Stress at Work).

In addition to epidemiological findings this model underwent careful testing in experimental and 'naturalistic' investigations. Single or combined scales measuring effort–reward imbalance at work were related to dysregulated hormonal profiles, altered cardiovascular responses, and markers of reduced immune system function (Chandola et al., 2010). Moreover, first intervention studies revealed that mental health improves following a theory-based work stress reduction program (Bourbonnais et al., 2011).

Taken together, the available evidence of research on violations of the strong principle of justice of exchange in core social roles, and specifically in the work role, documents elevated subsequent risks for several disorders, such as depression or cardiovascular disease. As social reward frustration is generally more frequent among people with lower socioeconomic status, and as these stress-related disorders follow a similar social gradient, interventions should target socioeconomically deprived group with priority. Such interventions are not restricted to the individual, group, or organizational level, but may include national labor and social policies that aim at improving justice of exchange in core areas of everyday life.

Conclusion

Experiencing justice or injustice in social life matters for human health and well-being. Although these experiences reflect people's subjective appraisals they usually evolve from unequal social exchange and social deprivation, triggered by disregard of notions of fairness and by violation of underlying social norms. Fairness as a social preference seems to play a relevant role in human evolution (Fehr and Fischbacher, 2003), and its disregard is likely to evoke strong negative emotions and stress reactions. In three areas of unequal social distribution, we demonstrated elevated risks of stress-related physical and mental disorders: income inequality, organizational injustice, and inequity of exchange in core social roles, such as the work role.

There is much room for extending this line of research in several directions. One direction concerns the comparative cross-country analysis of distributive injustice, for example, addressing access to basic resources including employment and good quality of work, social security, or environmental health. In another direction, the temporal dimension in terms of intergenerational justice of exchange may be explored. Furthermore, additional experimental evidence on the effects of microsocial inequity on brain functioning and behavioral responses is of interest. In terms of policy implications intervention studies are of primary importance as they demonstrate the potential benefit of reduced injustice in social life for human health and well-being.

Justice and Law

David Luban, Georgetown University Law Center, Washington, DC, USA

Abstract

This article proposes that the commonsense conception of legal justice is simply treating people as the law provides. Law, however, can be flawed from the standpoint of extralegal justice. In that case, the term 'legal justice' sounds like a misnomer – a wrongful appropriation of the terminology of justice viewed as a moral virtue. The article examines two avenues of response to this problem: first, theories that narrow the gap between legal and extralegal justice, and second, theories according to which the central virtue of legal systems is something other than justice. Among the former, the article discusses natural law theories, moralized theories of interpretation, equity, and certain forms of alternative dispute resolution. Among the latter, it discusses economic, pragmatic, and feminist alternatives to a justice-centered account of law's virtues.

Justice has been called the fundamental moral virtue of social institutions (Rawls, 1971). In similar fashion, 'legal justice' is the name commonly given to the fundamental moral virtue of legal institutions. Theorists through the centuries have differed substantially over what this virtue is, and what relation legal justice bears to other forms of justice. In its commonsense meaning, according to which legal justice means treating people as the law provides, legal justice helps ensure that people are treated consistently and predictably. At the same time, however, it seems unlikely that treating people as the law provides invariably means treating them justly in a moral sense, because the law is at best an imperfect instrument of corrective justice, distributive justice, or even elementary decency. Some theorists have responded to this concern by offering alternative accounts of legal justice. Others, of more skeptical bent, have doubted that legal justice has much to do with moral justice, either because they deny that legal institutions have moral aims, or more commonly because they believe that other virtues, such as economic efficiency, pragmatic problem solving, or compassion, are more fundamental aims of legal institutions.

The Commonsense Conception of Legal Justice

In its primary everyday sense, legal justice means treating people as the law provides. This view may be referred to as the commonsense conception of legal justice. Under the commonsense conception, law, rightly interpreted and correctly applied to facts determined rationally, yields legal justice. Indeed, 'legal justice' turns out to be nothing more than the name for the state of affairs in which law is rightly interpreted and correctly applied to facts determined rationally; the phrase has no legitimate meaning other than this. Under the commonsense conception, legal justice is roughly synonymous with legality itself. It is what most people mean when they speak of the 'rule of law,' an abbreviation for 'the rule of law, not of men.' Where the rule of men subjects people to the will of officials, who may be partial or capricious, the rule of law impartially subjects people only to the law itself (*see* Rule of Law (and Rechtsstaat)).

In Western philosophy, it was Plato (428–347 BC) who in his late dialogue *The Laws* first introduced the idea that human rulers should be 'slaves of the law.' Aristotle (384–322 BC) also endorsed the rule of law idea, in his *Politics* (Bk. 3, ch. 16); it is also Aristotle who, in *Nichomachean Ethics* (Bk. 5), provided the first systematic analysis of the forms of justice. Notably, however, Plato did not entirely endorse the rule of law. Drawing on the analogy of physicians who change their course of treatment when they find it is killing their patients (Statesman 295c–297c), he argued that officials should depart from legal rules when the good of the city requires it. The fear that rigid legality may lead to injustice haunts the commonsense conception of legal justice.

The commonsense conception raises large jurisprudential questions. How is law interpreted rightly? How is it applied properly? How are facts determined rationally? Competing philosophical schools offer various theories of legal interpretation; proceduralists disagree about how to adjudicate properly; and evidence law balances epistemological accuracy against investigative cost and the protection of personal rights. As a result, the commonsense view that legal justice means treating people as the law provides is not as straightforward as it seems. It is fraught with ambiguity – an essentially contested concept if ever there was one. The commonsense conception of legal justice turns out to be an entire family of conceptions.

Perhaps the most fundamental divide among theories of legal interpretation and law application exists between views that try to bind decision makers through nonmoral general criteria and views that require decision makers to exercise moral judgment. Leading examples of the former are textualism – the idea that laws must be interpreted according to the exact wording of their texts – and intentionalism, the idea that laws must be interpreted according to the intention of those who enacted them, ascertained through objective historical evidence. An example of the latter is the theory of the distinguished philosopher Ronald Dworkin (1931–2013), who believes that judges are required to interpret law in the morally best light it can sustain (Dworkin, 1977, 1986). (For further discussion on this point, *see* Legal Reasoning and Argumentation.)

Justice and Legal Justice

Regardless of how its ambiguities are resolved, the commonsense conception implies that legal justice will never be any better than the law itself. If the law itself is unjust, then treating people as the law provides will produce injustice. US Supreme Court Justice Oliver Wendell Holmes wrote in a letter, "I have

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86043-2

said to my brethren many times that I hate justice, which means that I know if a man begins to talk about that, for one reason or another he is shirking thinking in legal terms" (Holmes, 1929). Legal justice, understood as legality, differs essentially from what might be called extralegal justice. If Holmes is right that legal institutions do not deliver extralegal justice, then two rather disquieting conclusions appear to follow. First, the term 'legal justice' is fundamentally misleading: the word 'justice' in it really does not mean justice in the moral sense that is its home terrain. Second, there may be no reason to think of legal justice as a moral virtue at all. A good murderer is not good, and legal justice may be unjust.

Moreover, even when a law is just, inflexible application may yield outcomes in particular cases that are inequitable – unjust, in another everyday sense of the term – because of the peculiar facts of the case. Laws are general in scope, but, as Aristotle observes, even a good general rule may yield an unjust outcome when the case does not fit the rule. Thus, alongside the problem of unjust laws there is a problem of unjust outcomes. Both problems generate a tension between justice and legal justice.

The Natural Law Alternative to the Commonsense Conception of Legal Justice

The most ambitious approach to the problem of unjust law simply denies the possibility that law can be unjust. At the first blush, this sounds absurd, but the proposition that unjust law is not really law at all (*lex injusta non est lex*) has had powerful defenders in the so-called natural law tradition, among them St Augustine and St Thomas Aquinas (*see* Natural Law). The natural law argument may be put as follows. Inherent in the idea of law is the claim that the law creates moral obligations over and above whatever penalties attach to it. That is why a tax law is different in kind from a gunman's command to hand over your wallet, and lawful authority is not merely a 'gunman writ large.' The difference is that one does nothing blameworthy by evading the gunman, but it is commonly believed that tax evasion is wrong. If the law is unjust, however, the moral obligation vanishes, and with it the status of law (Soper, 1984).

The leading natural law theorist John Finnis (b. 1940) puts the argument somewhat differently. Legal systems are instituted for a purpose, namely, to promote the common good. The common good requires that there be lawmakers and law enforcers, who solve the various coordination problems that arise in organized society. Their role in fulfilling the common good is the sole reason that lawmakers and law enforcers have authority over others, and why others ought to obey them. The law-making authority therefore has an implicit limit: if legislators are not aiming at the common good, they have exceeded their authority, and the laws they enact are laws in form alone (Finnis, 1980). This was the same conclusion reached by the German theorist Gustav Radbruch in a famous argument that racist Nazi laws were no laws at all (Radbruch, 1946/2006).

The intuitive basis to the natural law argument is that every recognizable legal system is built around a core set of rules, such as the proscriptions of violence, theft, and fraud. These are moral requirements recognizably directed toward the common good; they flow from the nature of human society, and ultimately from human nature itself. They are 'natural laws' in the sense that reasoning from human nature seems to dictate that they belong in every legal system. To natural lawyers, the idea that any arbitrary set of rules could constitute a legal system is unrealistic, because it denies that reason itself reveals the core of natural law at the heart of legal systems.

The natural law position can be understood as an amendment to the commonsense conception of legal justice. Where the latter understands legal justice to mean treating people as the law provides, whatever that may be, the natural law conception understands the very character of law to be such that it cannot treat people in a manner inconsistent with natural law.

To the natural law argument there are at least two responses. The most prominent is the argument of legal positivists (*see* Legal Positivism). Positivists hold that law consists at bottom of nothing other than posits of the sovereign authority. Any valid enactment by the sovereign authority is law, whether or not it is just. From the positivist point of view, natural lawyers are merely playing definitional games when they insist that a duly enacted statute should not be honored with the title 'law' unless it is just. Taking away the label 'law' does not take away the problem of unjust law, because officials remain duty bound to treat people as the positive law provides. The commonsense conception of legal justice cannot be merely defined away.

Furthermore, even if the natural law argument is right that not just any capricious set of rules counts as law, and that only a system devoted to the common good will be recognizable as a legal system, it does not follow that every single law in a legal system is just: a system devoted to the common good can contain flaws and blind spots. The natural law argument applies most plausibly to entire legal systems, not individual laws. Perhaps a largely unjust system is not really law, but an unjust enactment of a statute in a largely just system is presumptively law. In that case, the problem of unjust law reappears within the natural law conception of legal justice.

The American philosopher Lon Fuller proposed a distinctive version of the natural law argument. According to Fuller, a legal system must satisfy eight procedural requirements, which he called 'the inner morality of law' and 'procedural natural law.' Enactments must be general in scope, public, prospective rather than retroactive, clear, consistent, relatively constant over time, capable of being obeyed, and enforced as written. Fuller believed that law serves as a baseline around which citizens organize their activities, and citizens must be able to know, understand, and comply with the baseline. The eight procedural requirements ensure that law satisfies these conditions. For Fuller, then, legal justice has more specific content than the commonsense conception – law must satisfy the eight procedural requirements – but less content than the traditional natural law view.

Fuller's eight requirements have been widely accepted as an analysis of the rule of law. Fuller also believed that any legal system satisfying the eight procedural requirements would be substantively just, but his efforts to demonstrate this ambitious conclusion are unpersuasive. American slave law satisfied the eight procedural requirements; so did many legal regimes that treated women as mere property of their fathers or husbands. Such legal regimes were procedurally just but substantively unjust, and most theorists agree that Fuller's theory of

'procedural natural law' fares no better than traditional natural law theories in eliminating the problem of unjust law.

Building Justice-Enhancing Devices into the Law

An alternative approach to the problem of unjust law concedes that unjust law is possible, but tries to narrow the gap between justice and legal justice by building into legal systems devices for bringing law into line with justice. Legal language can be interpreted flexibly rather than rigidly, or interpreted in its morally best light, as Dworkin proposes. Many legal systems permit statutes to be invalidated when they conflict with constitutional principles, which are often framed in broadly moralistic language. In European law, the principal human rights treaty must be interpreted in the way that most effectively protects human rights, even if that is not the most literal interpretation; that is because of the European Convention on Human Rights' "special character as a treaty for the collective enforcement of human rights and fundamental freedoms" (*Soering v. United Kingdom*, 1989, para 87). In the United States, juries have the power to nullify unjust law by acquitting a criminal defendant in defiance of the law. Officials, too, may decline to enforce unjust laws, nullifying them through a kind of benign neglect. Arguably, nullification defeats legal justice in the name of extralegal justice; however, some theorists have pointed out that the discretion to nullify law is itself sanctioned by law, and therefore may be regarded as an escape clause built into the concept of legal justice (e.g., Kadish and Kadish, 1973; Butler, 1995). Law must be administered, and because laws are stated in general form, officials will always have some discretion to determine when laws apply; thus, the power to nullify will always exist.

Devices like these, which are internal to the law itself, may well lessen the tension between justice and legal justice, but few theorists believe that they eliminate it. No method of interpretation is flexible enough to yield any desirable result, nor is every unjust law automatically unconstitutional. Furthermore, nullification is a device better suited to the exceptional case than to the rule itself.

Law and Equity

What about situations in which a law is just, but applying it strictly in a particular case yields an unjust outcome? Aristotle defines the word equity as "a correction of law where it is defective owing to its universality," and argues that justice requires that law should yield to equity. This, arguably, is what nullifiers are up to. In Aristotle's memorable image, rules of law should be like the soft lead rulers that builders use to measure irregularly shaped molding: "the rule adapts itself to the shape of the stone, and so too the decree is adapted to the facts" (*Nichomachean Ethics*, Bk. 5, ch. 10). (For further discussion, *see* Equity in Law.)

But while the utility of soft rulers is clear, soft rules are more problematic. In contemporary terms, Aristotle was arguing that law should consist of standards rather than rules. A law that says 'drive no faster than 100 km per hour' is a rule; a law that says 'drive at a reasonably safe speed' is a standard. Standards, unlike rules, are adaptable to facts in the case-by-case way that Aristotle recommends.

There are two problems with replacing rules with standards, however. The first is that standards are useful only when there is widespread social agreement on how they apply across a broad range of cases. Where no such agreement exists, law must resort to rules if it is not to become fatally vague. For that reason, mature legal systems always contain both rules and standards.

The second problem is that the shift from rules to standards will not eliminate the need to supplement law with equity. Standards, like rules, are general, and can therefore yield injustice in particular cases. For example, a driver rushing a stroke victim to the hospital may be driving faster than 100 km per hour and driving at an unsafe speed. If it seems unjust to punish the driver, that will not be because the speed limit takes the form of a rule rather than a standard. Rather, it is unjust to punish the driver because the emergency situation does not fit any universal speed limit, either a rule or a standard.

Perhaps, then, the universality of laws should be abandoned. The problem with this approach is that the universality of legal rules and standards is the hallmark of laws, distinguishing them from orders and directives. Furthermore, the virtues of legal justice lie precisely in the universality of law. Because law is general, legal justice treats like cases alike, and in that way it is fair and impartial; in addition, generality makes the law predictable, which allows people to plan their affairs around the law. Treating people as the law provides honors the values of fairness and predictability, whereas rule by decree undermines both these values.

Alternative Dispute Resolution

One way to reduce the tension between law and equity is to divert a dispute from the formal legal system to mediation, arbitration, out-of-court settlement, or other forms of alternative dispute resolution (ADR). Proponents argue not merely that ADR can resolve disputes more quickly, cheaply, and cooperatively than formal adjudication, but also that by particularizing outcomes to the unique facts of each case ADR creates higher quality justice – it creates something that looks more like equity than law.

Here as elsewhere the argument is very ancient. For Greek authors of the Homeric period, the word 'justice' (*diké*) was synonymous with a mutually agreeable settlement. In *The Laws*, Plato distinguished between the best judge, who destroys the wicked, the second best judge, who subordinates the wicked to the good, and the third best judge, who reconciles the contending parties with each other. Plato argued that in a real, nonutopian city the third best judge, the one who settles cases through compromise, is better than the other two (627e–628a).

However, the virtue of ADR and the settlement process – that ADR makes an end run around legal formalities – raises questions about how to evaluate the justice of settlements. Negotiations, which often turn on nothing but naked bargaining power, can yield outcomes fully as inequitable as trials. Furthermore, critics of ADR suspect that informal processes may reinforce unequal power relationships, and that the lack of formal protections will leave vulnerable groups even more vulnerable. Should the justice of a mediated settlement be evaluated against the standard of an ideally fair trial (the 'shadow verdict'), or an ideally fair

negotiation (the 'shadow bargain'), or something entirely *sui generis*? How are any of these standards to be determined? Does compromise promote extralegal justice, or does it merely compromise legal justice? Such questions yield no easy answers. (For further discussion of this point, *see* Mediation, Arbitration, and Alternative Dispute Resolution (ADR); Negotiation and Bargaining: Role of Lawyers.)

Origins of the Conflict between Justice and Legal Justice

How grave the tension between extralegal and legal justice is depends on what extralegal justice consists of. Philosophical theories of justice differ dramatically from each other (*see* Justice: Philosophical Aspects), and none commands anything resembling a consensus. When Holmes wrote 'I hate justice,' his skepticism can be read as a complaint about the vagueness and debatability – hence, the contentlessness – of the concept of extralegal justice.

Yet despite the philosophical controversies, there is a recognizable Western concept of justice of which the philosophical theories may be said to offer alternative interpretations or conceptions. This concept draws on the two chief sources of Western moral thought, Greek philosophy and the Bible.

For Plato and Aristotle, and likewise for the biblical authors and redactors, justice is primarily a virtue of persons rather than of institutions. Thus, Plato's *Republic* investigates justice in the city only because Plato believes that the city is a plausible analogue to the individual soul, his real topic of interest; so too, Aristotle places his account of justice in his treatise on ethics rather than in his treatise on politics. In the Bible, a just community is simply a community filled with just people. In this respect, the classical and biblical sources differ profoundly from contemporary theorists, who treat justice as a property of institutions rather than of persons.

It was Aristotle who first observed that the words 'unjust' and 'just' are ambiguous – the former refers both to 'the lawless man and the grasping or unfair man,' and similarly the latter refers both to the law-abiding and the fair man (*Nicomachean Ethics*, Bk. 5, ch. 1). One form that the virtue of justice assumes, then, is obedience to the law. Related to this form are special virtues of officials – to punish lawbreaking, and to judge impartially (which is a requirement found both in the Hebrew Bible and in Aristotle).

What about extralegal justice? Both the Jewish and Christian traditions locate the core ideal of justice in the Golden Rule and the injunction "Love your neighbor as yourself" (Leviticus 19:18; Matthew 22:39), which commentators often regard as alternative formulations of the same duty. In addition, both traditions lay special emphasis on the injustice of neglecting or oppressing the poor – a recurrent theme among the biblical prophets. The Hebrew word for almsgiving, *tzedakah*, derives from '*tzedek*,' the word for justice. *Tzedakah* is a duty of the just individual, and a community will be unjust to the degree that it neglects the needy. In contemporary discussions, people often use the term 'social justice' in precisely this way, to express a social duty of justice to the poor. Similar themes appear in non-Western religious traditions as well (including a version of the Golden Rule in the Analects of Confucius).

This sense of extralegal justice as solidarity with the least fortunate will inevitably generate conflicts with legal justice. Even within Leviticus 19, the duty to care for the needy lies in tension with the duty of judges not to favor the poor. Furthermore, as functionalists argue, laws aim to maintain and preserve a social order; law is therefore an innately conservative institution, whereas the prophetic conception of social justice is innately utopian and radical. One cannot really expect that laws in any society will be systematically formulated to enforce wealth transfers from the prosperous and powerful to the poor and powerless.

There is another reason as well to anticipate divergence between legal and extralegal justice. Since Aristotle, it has been traditional to distinguish distributive justice from corrective justice. The former concerns fundamental questions of distribution in society; the latter deals with the rectification of injuries, both civil and criminal. Legal institutions such as courts deal principally with issues of corrective justice, and have very little to do with distributive justice (which is not to deny that legal decisions often have distributive effects). As writers from Aristotle onward have observed, corrective justice may run contrary both to moral virtue and distributive justice. For, if a good person accidentally injures a wicked one, or a deserving poor person injures an unjustly wealthy one, the injurer will owe compensation, even though in the former case the good person may be ruined for the sake of the bad, and in the latter case the distribution of wealth becomes even more lopsided than it was before. Legal institutions take established distributive principles and patterns as a given, regardless of whether they are just. In this sense, then, even when courts achieve corrective justice, they may well reinforce distributively unjust practices.

Alternatives to Legal Justice

So far this article has surveyed four conceptions of legal justice: the commonsense conception, according to which legal justice secures the goods of impartial consistency and predictability in the law; the traditional natural law conception, according to which legal justice secures the common good; Fuller's 'procedural natural law,' according to which legal justice conforming to the eight canons of lawmaking provides an intelligible baseline against which people may order their own affairs; and the Aristotelian idea that genuine legal justice combines universal legal standards with equity. None of these is able to relieve the tension between legal and extralegal justice. The question remains whether other alternatives do better. Several alternatives have become prominent in contemporary debates.

Law and Economics

One response is simply to deny that achieving extralegal justice is an important aim of legal systems. A particularly influential contemporary version has been offered by law and economics theorists. According to Richard Posner (b. 1939), a founder of law and economics, the aim of legal systems is to maximize aggregate social wealth. If legal rules systematically fail to maximize social wealth, disputing parties could realize shared gains by bargaining around the law; inevitably, then, the law

gravitates toward wealth-maximizing rules. Furthermore, wealth maximization is a normatively desirable aim, better than utilitarianism because it cultivates productive virtues rather than pleasure seeking (Posner, 1983). Critics, however, have found both the descriptive and normative claims of law and economics exaggerated. Inefficient legal rules sometimes linger for centuries, and the argument that a law prohibiting murder or rape can be justified only if it can be shown to maximize social wealth seems unsupportable (Dworkin, 1980; Kronman, 1980). (For further discussion of this point, *see* Law and Economics: Empirical Dimensions.)

Pragmatism

Another prominent alternative to the commonsense conception of legal justice is pragmatism. As one proponent defines pragmatic adjudication, "a pragmatist judge always tries to do the best he can for the present and the future, unchecked by any felt duty to secure consistency in principle with what other officials have done in the past" (Posner, 1998: p. 237). To the objection that this is an invitation to lawlessness, pragmatists respond that doing the best for the present and the future will in some cases require the judge to apply law and precedent in a rigidly formalistic manner; in other cases, however, pragmatism requires judges to look past formalities.

Pragmatists collapse legal justice into extralegal justice, where the latter is understood as achieving the best consequences overall. In one respect, pragmatism descends from the legal realists (*see* Legal Realism), who argued that legal formality is merely a disguise for implicit policy choices, which should be made explicit and be guided by concern for consequences. In another sense, pragmatism represents a radical version of Aristotle's plea for context-specific equitable standards. The attractions of pragmatism are plain, but the general objection to broad standards applies in an acute form to pragmatism: there will seldom be agreement on what 'doing what is best for the present and the future' requires in any controversial case; thus, the virtues of predictability, transparency, and treating like cases alike will erode from the law.

Feminism

Feminists influenced by the work of psychologist Carol Gilligan have argued that the ethic of impartial justice is a quintessentially male construct – one that is in no way superior to the feminine 'ethic of care.' To illustrate the ethic of care, some feminist legal scholars have fastened on the image of Shakespeare's Portia, who pleads that the 'quality of mercy' should replace rigid legal justice. The ethic of care focuses on repairing relationships and is directed toward individual needs rather than rules, policies, or the best overall consequences; unsurprisingly, this leads some proponents of the ethic of care to favor ADR over formal adjudication. On the other hand, other feminists caution that the ethic of care is part of legal justice rather than an alternative to it; conversely, care itself becomes corrupted without the virtues of consistency, integrity, and evenhandedness – precisely the virtues promoted by legal justice in its commonsense conception (West, 1997). (For further discussion on this point, *see* Feminist Legal Theory.)

Conclusion

It is often unclear whether law and economics, pragmatism, and feminism are intended as alternatives *to* legal justice or as alternative analyses of legal justice. In a sense, all the theories surveyed here are responses to two fundamental tensions. The first is the tension between the rule of law, which subordinates particular cases to general rules, and the moral demand to treat particular cases according to their individualized merits. The second is the tension between the values of consistency, predictability, and stability that legal justice serves and the more Utopian values implicit in broader notions of justice. It may well be that no intellectual approach can eliminate this tension, or reconcile the competing senses of the word 'justice.'

Justice, Conflicts, and the Justice of Conflict Resolution

Leo Montada, University of Trier, Mozartstr, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Whereas concerns for justice are universal, views of what is just and what is unjust are not universally shared. Divergent views of justice often cause social conflicts. Frequently, the parties involved in conflicts are convinced that their own view is the solely valid one. As we have no access to an objective truth about justice, conflicts may be reconciled by the judgement of an authority accepted by all parties or by a negotiated agreement between the parties. Agreements are just when the parties are equally free in their decision and equally informed about all relevant facts and possible outcomes.

Justice – A Universal Concern of Humans

Claims for justice and protests against injustice are ubiquitous in social life. Political movements, revolutions, and wars are inflamed by experienced or perceived injustices. Justice is debated in all fields of politics. The courts are swamped with lawsuits aimed to enforce supposedly just entitlements. Resentment of injustice is at the core of conflicts in all contexts of life from the domestic to the public domain. It is hard to cope with a fate that is perceived as unjust.

The scope of concern for justice becomes obvious by the spectrum of subjects that are evaluated as just or unjust: *distributions* of wealth and poverty, opportunities and risks, rights and duties, etc.; *social interactions and relations* where, for example, goods and services, love and loyalty, or hostilities and retributions are exchanged; *retributions for offenses*; *valuations of achievements and failures*; *constitutions and laws of states, the bans and rules of religions*; *social roles, rules, and conventions in cultures and communities*; and *procedures in elections and in decision making*.

The Justice Motive

Appraisals of justice emotionalize and have a motivational impetus. Humans have a justice motive; they are averse to injustice (Ross and Miller, 2002). This assumption does not fit to the conception of man as homo oeconomicus implying the assumption that self-interest is the cardinal human motive. The following examples lay out some of the differences between these two conceptions of man.

No doubt, the 'flag of justice' often serves to mask self-interest (Montada, 2003). Politicians may promise to fight against some injustice hoping to thereby raise their own popularity. Employers may care about the productivity of their employees, which declines when these feel treated unjustly. However, a merely strategic concern for justice proves that the actors believe that justice is an important concern of other people, which they try to abuse in a 'parasitic' way for their selfish goals (Elster, 1989).

Rich empirical evidence is available for the fact that people care about justice also when this does not serve their self-interest. Resentment is not only evidenced in cases of self-experienced injustices, but also in cases of injustice suffered by foreign people all over the world, e.g., by victims of natural disasters, poverty, violence, negligence, or despotism. Feelings of existential guilt were observed with people living in fortunate conditions when they became aware of the bad fate, the harm, and hardships suffered by foreign people. Both resentment and existential guilt stimulate prosocial commitments aiming at reducing these injustices (Montada, 2003).

Using experimental approaches, such as the Ultimatum or Public Goods or Resource Dilemma games, innumerable studies in various cultures have shown that a majority of people surrender personal advantages and take considerable costs only to prevent or to retaliate unjust selfish advantage taking of other actors. These findings can only be understood by assuming justice motives (Fehr and Gächter, 2002; Fehr and Schwarz, 2003). The justice motive cannot be reduced to self-interest, it is a primordial motive.

Divergent Views about Justice Cause Social Conflicts

While the justice motive is universal, the views of justice are not at all universally shared. Whatever the target of valuation may be – distributions, social exchanges, evaluations of deeds and misdeeds, achievements and failures, policies, laws, and other normative standards, procedures in elections and decision making – we find divergent views. The convictions vary between cultures, collectives, social milieus, and individuals when specific cases are appraised and also when general maxims of justice are at stake, e.g., the various principles for just distributions (Montada, 2012).

Conflicts may be carried out constructively, e.g., by rational discourses about diverging convictions and positions. Quite often they are carried out destructively. By far not every action powered by justice motives is commendable. Under the flag of justice, dire wrong is done. Frequently, actors 'justify' their violence, crimes, selfishness as retaliation of injustice or as prevention of expected injustice (Montada, 2007). Since Plato, justice was valued as one of the cardinal virtues in the antique and medieval philosophy. The justice motive, however, cannot generally be valued as a virtue. To be a virtue it needs cultivation, namely, the readiness and the competences to reflect on the validity of one's own convictions and those of others.

We are speaking of justice in the singular – *the* justice – as if one single view of justice would be the valid one in general or

in a concrete case and had to be acknowledged and shared by everybody else (Rüthers, 1991). And we tend to prefer mates, friends, and peers who share our own convictions. Many people have normative convictions that they believe to be 'indisputably true' or even 'sacred' and 'not negotiable.' They may be shared by more or less large collectives, they are, however, not shared universally.

The belief of justice as universal truth is to be found in religions – most of the bans and rules of religions can be understood as norms of justice. However, different religions hold different bans and rules. It is also to be found in political philosophies. These, too, hold different maxims of justice, e.g., egalitarianism, liberalism, social welfarism, or utilitarianism. No one is universally acknowledged. Consequently, the question of what is just and what is unjust is debatable and may cause social conflicts. Within states, communities, and further social units, conflicts are less frequent when views about justice are widely shared and when the justice of institutions as parliaments and courts is widely acknowledged within the population (Würtenberger, 1984). In pluralistic populations, divergent views of justice and divergent attitudes toward authorities and institutions are the rule.

The Spectrum of Justice Principles in Various Subject Fields

Equality is widely considered as the basic principle of justice (Gosepath, 2004). What does equality precisely mean? Equal freedom for all, equal opportunities or equal outcomes (cf Barry, 1989; Kolm, 1996; Schmidt, 2000; Sen, 2010)? Human beings are different in many respects. Is everybody to be treated equally, does everybody have equal rights and duties or are only equals to be treated equally and have equal rights and duties as Aristotle has postulated? Many debates about justice start with the question which inequalities are relevant and to be considered in the evaluation of justice and injustice.

Distributive Justice

For instance, which inequalities can be seen as relevant concerning the *just distribution* of goods, burdens, rights, duties, etc.; gender, age, social status, kinship, nationality, merits, skills and expertise, needs? Should various relevant inequalities be accounted for in combination? How relevant are responsibilities for needs, losses, damages, injuries, diseases, etc., with respect to distributive justice? These questions are debated by philosophers, in political arenas and in many public and private contexts.

Walzer (1983) proposed the concept of *complex equality*, meaning that distributions in different spheres of justice (e.g., material wealth, social recognition, political power, education, kinship and love, hobbies, etc.) are not perfectly correlated. Thus, a lower rank in one sphere may be compensated by a higher rank in another. Taking into account that the subjective importance of these spheres varies between people, the subjectively experienced and perceived overall inequality in a population may be much lesser than 'egalitarians' presume and criticize as unjust.

Justice in Social Exchange Relationships

The equality criterion for appraising justice can also be found in some modified forms in other domains of social and societal life. In exchange relationships, reciprocity and equity are prominent principles. Social exchanges have been regarded to be just if reciprocity is established (Gouldner, 1960). This is true for positive exchanges, where equal mutual advantage is the normative standard, as well as for negative exchanges, which are often described by the metaphor of 'an eye for an eye and a tooth for a tooth.'

Same as in the domain of distributive justice, the actors in exchange relationships may not be equal, for instance, with regard to their needs, abilities, wealth, burdens, social roles, opportunities, etc. These and further inequalities have to be considered when the justice of exchanges is evaluated. In many relationships, equal mutual advantages are neither possible nor expected. Nevertheless, the exchange relation may be evaluated as just, especially when the *equity principle* is applied or when social role relationships are assessed.

Equity means equal ratios of investments/costs and outcomes/benefits of all parties involved in exchange relationships. Actually, the subjective appraisals of these ratios, not the objective balances are crucial (cf Tyler et al., 1997). Subjectively, different exchanges (goods, services, love, respect, trust, loyalty, harm, negligence, hostilities, etc.) may be focused on and balanced. Indirect and chained exchanges may be included in the subjective balances. In many close relationships, subjectively all provided benefits and services may be experienced as compensated by gratitude or by love. In social role relations, too, equity does not mean equality of reciprocal exchanges. For example, teachers will be motivated to give their best and feel justly gratified by their pupils' progress. The kind of relationship is crucial. On the marketplace, the exchange relations are not the same as in employment contracts, in families or in friendships. Consequently, the justice standards are not the same.

Retributive Justice

The preliminary question is: What is considered an offense, a crime, a sin? The answers vary a lot in national or religious codes and in the normative standards of cultures and communities. Consequently, the answers are debatable in terms of justice. Further questions are: What should be done in case these norms are violated? Are the offenders to be punished or to be educated? Who is to blame for the offense: the offenders, their families, or the social system? How is the punishment of an offense to justify: as retaliation, as deterrence, as rehabilitation? These questions, too, are debatable in terms of justice.

What are just assessments of offenses (Darley, 2002)? The main principle of *retributive justice* is specified as proportionality of guilt for misdeeds and their punishment. Again, inequalities between the actors and the specifics of the action context are to be considered. The guilt of offenders may be qualified by their life history, their living contexts and by situational specifics, which may qualify their responsibility, e.g., provocations by the victims (Auhagen and Bierhoff, 2001). Impartiality of verdicts means that the same standards are applied to similar offenders and similar offenses.

The focus of *restorative justice* is not retribution of the offense but support for the victims and reintegration of the offenders into society (Rössner, 2004). This approach frequently brings offenders and victims together. The offenders shall become aware of the effects that their offense had on the victims. They get an opportunity to apologize and to make amends. In cases of an interactions history between offenders and victims as in cases of mobbing, the victims may learn whether and by which behavior they may have provoked the offenders.

Procedural Justice, Just Decision Making

In view of the broad spectrum of options for appraising and constructing justice in various fields of social life, conflicts about justice can be expected. Depending on the kind of conflicts and the social system, various ways for their settlement are available: lawsuits, arbitration, negotiation, mediation, decision making in parliaments, organizations, and communities. In all these contexts, procedural justice gains eminent importance (Ackermann, 1980). A prerequisite of accepting a decision as just is the perceived legitimacy of decision-making authorities or bodies.

Moreover, those who are affected by decisions value the impartiality and the objectivity of authorities and decision making bodies as criteria for justice (Leventhal, 1980). Above all, they want to have 'voice,' meaning the opportunity to present their views and claims in the process of decision making (Thibaut and Walker, 1975). Well confirmed by empirical research is the fair-procedure effect (cf Tyler et al., 1997), meaning that perceived procedural fairness helps the parties to accept decisions or outcomes that are less favorable than they had expected and hoped for. Decent and polite treatment by authorities may add to this effect (Lind and Tyler, 1988).

The Justice of Constitutions and Codified Laws and Ethics

Justice convictions are also crucial in appraisals of constitutions, legal codes, religious bans, and rules. These and further bodies of normative maxims and rules exhibit large divergencies that give reason for disputing about their justice. Every law, every normative maxim can be criticized on the basis of some justice principle. Legal codes may violate human rights or the bans and rules of some religion. The charter of human rights contravenes the normative traditions of various cultures. For instance, it is open to question whether the dignity of human beings may be determined universally or whether it may be specified according to culturally shared values or according to individual values formulated in every social interaction up to living wills? Different cultures have diverging conceptions of justice, rights and duties, standards for respectful behavior, honor, etc. Cultures are definable by their specific morals and manners – codified or not.

Efforts to Remove Injustice May Create New Injustices

It is easier to criticize some injustice than to establish justice within social and societal systems. Efforts to correct one injustice may result in new injustices as illustrated by a few examples. (1) Affirmative action policies are justified as just compensation for the unquestionable historical disadvantages of women in the labor market. Surely, there are good reasons for removing these disadvantages. However, it is disputable whether it is just to privilege young women who have personally not been disadvantaged so far in competition with young men who have personally not been privileged. (2) Justice for the defendants may mean injustice for the victims of crimes. When the 'benefit of doubt' is granted to the defendant – doubtlessly a significant progress in the history of criminal law – the victim's claim for justice may be violated, assuming that the victim has no doubt that the defendant is guilty (Orth, 2000). (3) Sentences may be deserved and just retributions for offenses, but they bear the risk of unjust social discrimination of people close to the offenders, for instance their children. Looking at the branched systemic effects of every intervention, it is not easy to avoid new injustices. Efforts to establish justice have to be diligently checked for the risks of new injustices.

Injustice and Conflicts

At the core, all social conflicts are justice conflicts. People expect that others respect the normative standards, entitlements, and claims that they believe to be just. Conflicts result from violated normative expectations on how other people, agencies, etc., have to behave, from violated or disregarded claims, whatever their normative basis may be: human rights, a legal code, the codex of a religion, a formal or an implicit contract, or good manners that are valid in a culture. Crucial is the fact that actors consider their own convictions as legitimate and as rightfully to be claimed.

Perceived injustices, not incompatibilities instigate social conflicts. Incompatible goals, plans, opinions, etc., may bear the risk of conflict, but only in case that actors violate the normative expectations of others. Diverging views may be appreciated as worthy of consideration or else as disrespectful, as withdrawal from the community. Diverging goals may be considered as legitimate or as an offense. Diverging religious beliefs may be tolerated as a matter of personal freedom or condemned as a sin or a sacrilege. Fair competition is not a social conflict. If all actors in competitive markets and sports are considered to behave legitimately, frustrations and losses are possible but they do not evoke resentment. There are winners and losers but not victimizers and victims. The losers have nothing to reproach the winners for.

Perceived injustice instigates resentment, reproaches, wishes for retaliation, or claims for compensation. In conflicts, people claim justice for themselves or for others for whom they feel sympathy or responsibility. They react with resentment when they view the perpetrating actors as responsible, and when they do not see a convincing justification for the norm violation. Conflicts will become manifest when the actors are blamed and do neither confess nor apologize for their misdemeanor nor excuse or justify their behavior convincingly. In manifest conflicts, the parties justify their own behavior and reproach the behavior of the others.

Conflicts and Justice

Looking at all the divergent views of justice, we have to conclude that conflicts are unavoidable. When conflicts are not reconciled, but carried out destructively, they may be costly for one or for all parties. They may be a mortgage for future exchanges and end in lasting hostility. Conflicts may also be an opportunity to recognize and remove injustices, to establish a sustainable peace, and to create productive social relationships. Using the right procedures, conflicts may trigger productive developments in social and societal life.

Justice by the Settlement of Conflicts

If the assumption is valid that social conflicts basically result from incompatible normative expectations or claims, making conflicting convictions converge is the self-evident strategy for settling conflicts. This point can be illustrated by the fact that sincere apologies by an offender have a pacifying effect. As Goffman (1971) has emphasized, by apologies the perpetrators express that they fully share the victims' normative view of the case. They affirm the violated norm as valid, they admit having offended the norm, to be responsible for their action or neglect, and to be blameworthy because their offense was not justified. Sincere apologies reconcile victims (as well as judges and observers) and reduce their resentment and desire for retribution (Ohbuchi et al., 1989). Thereby, a complete consent about the origin of the conflict is expressed, and the conflict is settled.

Convergence of normative convictions can be attempted by *normative discourses*. Discourses must not have the objective to find 'the' normative truth. In the mediation of conflicts they merely serve to convey the insight that good reasons can be put forward not only for one's own views and claims but also for the opponent's views and claims, and also for further stances that could be taken in the case. Normative dilemmata can be disclosed. In discourses, the conflict parties get motivated to seek not only arguments in favor of their own position but to deliberate also on counterarguments and arguments in favor of the position held by the opponents (Montada, 2012).

Settling conflicts is made easier when the opponents acknowledge that divergent norms or principles of justice may be advocated with good reasons, and, consequently, that neither party is solely right or wrong. If the opponents recognize that their conflict reflects a normative dilemma, they no longer view the position of the other side as completely illegitimate and their own position as the solely legitimate one. This is the reason why sacred, not negotiable normative positions are a big problem for the mediation of conflicts.

For example: Which employees should be dismissed first when business is running low? Many criteria may be deemed just: seniority, acquired merits, abilities, current performance level, need of the job for the support of a family age, wage level, etc.? Or should nobody be dismissed and the wages of all employees cut back? For each of these criteria plausible arguments and counterarguments may be pleaded.

In normative discourses, the conflicting positions or claims for justice are both supported and criticized. When good arguments are put forward, the opponents may qualify their views and claims. They recognize that for none of the conflicting claims exclusive validity can be claimed. It is the wisdom of institutions to consider and integrate various principles of justice in their regulations and decisions (Elster, 1992). The social market economy, for instance, is an attempt to harmonize the right of all citizens to free economic activities with the maxims of the social welfare state. Rawls' 'Maximin principle' is also a suggestion to combine the freedom to economic activities – which produces common wealth – with the entitlement of every citizen to participate in the common prosperity (Rawls, 1971).

Settlement of Conflicts by Just Contracts

Only a just peace is a sustainable peace – an unjust settlement of a conflict would cause new conflicts. However, not 'objective justice' is required for peace, but 'intersubjective justice,' meaning that all parties consider the settlement of their conflict to be just. Sentences and decisions by authorities carry the risk of producing winners and losers. The losers may believe to be treated unjustly. Settling conflicts by an agreement, by a contract, is the preferable option.

Just and Unjust Contracts

Contracts are regarded to be just when the parties are equally free to consent or not to consent and when the parties are equally well informed about all relevant facts and risks. This does not mean objective justice but intersubjective justice. A contract that the parties have agreed upon freely and well informed cannot be unjust to one of the parties. Justice would be at risk if relevant information had been withheld from one of the contracting parties, if pressure had been exerted, if one party had not been free to refuse the contract on account of some predicament, e.g., neediness. Therefore, unequal power, unequal neediness, unequal abilities to grasp complex information may jeopardize the justice of agreements.

Because contracts are of eminent importance for peace in social life, many legal norms have been established which specify the obligations of the contracting parties. In many states, legal rules have been established to protect the supposedly less powerful or less informed parties in business contracts. These risks can be reduced if the agreements are negotiated under the guidance of mediators who have the duty to actively balance such inequalities. Mediators also have to take care of the justice of contracts with regard to affected third parties.

Since Hobbes 1648/1970, equal freedom and equal information have also been the core idea in *contract theories of the state* (cf Kersting, 1994): Free citizens agree upon the constitution and the legal code of a state. This agreement constitutes the justice of the constitution and the legal code. According to this model, majority decisions in parliaments bear the risk that the losing minority and many citizens consider it as an unjust imposition.

In the settlement of conflicts, the opponents are considered autonomous to negotiate an agreement. However, appraising the justice of contracts would be incomplete without having a look at their *impact on third parties*. Adverse effects on third

parties would raise new justice problems. Contracts may be fair with respect to the exchanges between the contracting parties but may be seriously unfair with respect to third parties or a community as, for instance, cartel agreements that may be fair for the contracting parties at the expense of others. Therefore, it is prudent to expand the view from the contracting parties to the impact of an agreement on third parties and the public. Contracts at the cost of third parties are externally unjust and a cause for new conflicts. In conflict mediation, it is a wise rule to think of all third parties who may be affected by an agreement and to reflect their legitimate concerns.

Just contracts are binding, they are to be observed. This is the normative premise for making a contract. Typically, contracts are concluded on the base of assumptions about the future. Sometimes, these outcomes turn out to be wrong. If one of the parties has deceived the other one by false information the contract may be contested. What about erroneous assumptions that do not result from a deception? The parties to a contract are well advised to make explicit their shared assumptions as a base of the contract and to include the clause to adjust the contract in case that these turn out to be wrong. To ensure that contracts are just in the long run it is opportune to plan an evaluation of the feasibility and productivity of a contract and include the option to adjust and optimize the agreement in view of new facts, new insights, and new views of justice. *Adjustable contracts* are preferable to strictly and for all times specified ones because they allow to avoid injustices that have not been foreseen. This is also true for the laws and the institutions of a state, which have to be adjusted to new facts, to changed needs and preferences within the population, to changed views of justice, etc.

In the mediation of many *conflicts* (Deutsch, 2006; Montada and Kals, 2013), adjustable contracts are recommendable. The opponents should be made aware of the fact that their agreement is based on assumptions and expectations, which may turn out to be wrong or incomplete, and of the fact that they may have not considered all relevant aspects and questions and not all options for reconciling their conflict by an agreement. Therefore, the option may be considered to evaluate the current agreement after an appropriate period and to adjust it if this would be opportune with the same sense of fairness and the same climate of cooperation established in the actual mediation.

Summary

Humans universally care about justice, but their views of what is just are divergent. People tend to view their own convictions as the true or valid ones. We neither have cognition of an objective truth about justice nor authorities whose opinions would be acknowledged universally. Divergent convictions are causes for conflicts. Basically, all social conflicts are justice conflicts triggered by violations of subjectively just claims and expectations of how others have to behave.

If the parties in a conflict have trust in the justice of an authority or an institution they may appeal to them for settling the case. Conflicts may also be settled by an agreement or contract. An agreement is just between the parties when they have equal freedom of decision and equal information about relevant facts and expected outcomes. Whether an agreement is just or unjust with respect to affected third parties has to be examined case by case. Whether the agreement will come up to the expectations of the parties cannot be taken for sure. Including an evaluation of the agreement after an adequate period of experience offers the option to adjust it consensually.

Justice: Philosophical Aspects

Abstract

Justice is predicated mainly of three kinds of *iudicanda*: *subjects* (persons and collectives), the *conduct* of subjects, and *social rules*. Recent discussions have focused on *social justice*, concerned with social rules. Here John Rawls's seminal theory has biased the discussion toward purely recipient-oriented theorizing, considering solely how human beings fare under various social rules. An alternative approach would also consider how we are treating one another, making morally significant our specific roles in imposing social rules and the causal pathways on which such rules affect people.

Introduction

Justice is a central moral notion, associated with fair and impartial decision procedures (*procedural justice*) and with persons and groups being treated even-handedly (*formal justice*, treating like cases alike) and in a morally fitting way (*material* or *substantive justice*). The demands of justice are frequently presented as uncompromising and strictly required, in contrast to the more flexible – and sometimes opposing – demands of mercy, charity, humanity, decency, beneficence, kindness, and equity, which may be merely supererogatory.

Justice is predicated mainly of three kinds of *iudicanda*, namely, *subjects* (persons and collectives), the *conduct* of subjects (actions and omissions, such as accusations, refusals, policies, and wars), and *social rules* (including social institutions, laws, norms, practices and procedures, economic regulations, and educational and health care systems). In recent decades, discussion has focused on *social justice*, which is concerned with the third *iudicandum* of social rules.

Justice is often differentiated by theme. Thus *distributive* justice governs the assignment of benefits and burdens (such as rights, duties, property, income, and taxes), *commutative* justice governs trades and exchanges, and *corrective* and *retributive* justice govern, respectively, compensating the victims and punishing the perpetrators of prior wrongdoing. *International* justice is typically viewed as a separate area, in which the four mentioned themes are overshadowed by reflections on the just use of force. Just war theories are generally organized around two topics: just cause in going to war (*ius ad bellum*) and just ways of fighting a war (*ius in bello*). Kant adds a third topic: the just way of concluding a war so as to lay the foundation for a stable peace (*ius post bellum*, Kant, 1996, §58).

The manifest complexity of the notion of justice makes it doubtful that any unified account of justice can be adequate across *iudicanda* and themes. In response to such doubts, it is tempting, as numerous historical examples attest, to simplify matters through reductionist moves. One such move, prominent among deontological conceptions of ethics, is to reduce judgments of character to judgments of conduct, perhaps by holding that a just subject is one stably disposed toward just conduct, as independently specified. (One may object that the justice of subjects is in part a function also of their inner states: of the feelings and attitudes of individuals and the internal mode of organization of organized collectives. Thus, the city of Athens may be called unjust not merely on account of its conduct toward Socrates and the Melians, but also on account of the severe disadvantages its laws inflicted upon women, metics, and slaves.) Following Aristotle (1985), some conceptions of ethics have proposed the reverse: to reduce judgments of conduct to judgments of character. Just conduct is, then, conduct that a just agent (independently specified) would engage in. Locke (1960) and Nozick (1974) have proposed a third kind of reduction: social rules are just if and only if they were, or at least could have been, established through just conduct. Conversely, Rawls has suggested that persons and conduct are just when they support and obey applicable just social rules or help establish just social rules insofar as such are lacking (Rawls, 1971, 115, 334).

Other reductionist attempts seek to reduce judgments about various kinds of *iudicanda* to judgments about states of affairs. One consequentialist reduction of this sort holds that subjects, conduct, and social rules are just in proportion to their tendency to promote the overall goodness of the world or whatever part thereof they are specially responsible for. To be discussed in this article, John Rawls offers a sophisticated such reduction of judgments about social institutions to judgments about distributions.

The plausibility of such reductions depends on the overall plausibility of the theory of justice in which they are embedded, which in turn depends on whether the evaluative and normative judgments derivable from this theory are morally sound. So far no detailed theory of justice, reductionist or otherwise, has managed to cover several themes and kinds of *iudicanda* in a plausible way. Contemporary writers have therefore sought to develop more limited conceptions of justice. The paradigmatic effort in this vein, that of Rawls (1971), is focused narrowly on how distributive justice might be instantiated in the most important and pervasive rules, constituting the *basic structure*, of a self-contained society.

The Theory of John Rawls

A criterion of justice should entail plausible absolute and comparative judgments about feasible basic structure designs, actual or proposed. Rawls seeks a criterion that, in addition, facilitates real-world agreement among the citizens accepting it on how to maintain or reform their shared social institutions.

This second desideratum speaks against any criterion that, like the principle of utility, is too difficult to apply and hence too easily abused. Rawls seeks the morally best *public* criterion of social justice.

His central idea is to answer this moral question through a prudential one: morally best is that public criterion of justice that prospective citizens would choose on prudential grounds. The criterion and any basic structure designs based on it should be as good as possible for the persons living under them; nothing else need be considered. This central thesis is, of course, itself a moral claim – to be developed and examined in what follows.

Citizen's interests and preferences vary and are shaped by the actual basic structure design of their society. For his prudential question to have a determinate answer, Rawls therefore needs a vantage point that attains some independence from the status quo and also ensures agreement. This vantage point is the *original position* – an imagined deliberation among *parties* who, acting in the interest of prospective citizens, are to agree on a public criterion of justice without knowing, due to a *veil of ignorance*, the distinguishing features (endowments, tastes, needs, desires, creeds, and values) of their clients or even the natural and historical context of their clients' society.

To have grounds for deliberation, the parties need some information about their clients' interests. Rawls makes them assume that all clients have three interests, which he portrays as closely connected to their role as citizens in a democratic society and hence as not biased toward any particular religious, philosophical, or ethical worldview or way of life. Rawls calls these the *three higher-order interests*, suggesting that they are interests in the content and fulfillment of other interests (like second-order desires are desires about desires) and also are deep, stable, and normally decisive. These interests are (1) to develop and exercise a sense of justice, which involves a sincere allegiance to some conception of justice (whose content remains unspecified so as not to prejudge the parties' decision); (2) to develop and exercise the capacity to form, to pursue, and rationally to revise a conception of the good; and (3) to protect and advance one's particular conception of the good (Rawls, 1993, 19, 74). The main question in the original position is, then, which *social order* – consisting of a public criterion of justice and of the basic structure designs this criterion would actually bring forth in various alternative contexts – affords the best prospects for citizens' higher-order interest fulfillment?

Rawls makes the dramatic claim that the parties would, because of their severely limited information, make their choice pursuant to the *maximin rule*, seeking to optimize the worst social position that the public acceptance of their criterion might generate. They would examine candidate criteria of justice, asking of each how badly off, in terms of the three higher-order interests, persons might come to be in societies in which it is the accepted public criterion of justice. And they would prefer the criterion that promises the higher floor (i.e., the *max*imum *min*imorum), even if it would also lead to a much lower ceiling and average.

Rawls argues that the parties would favor a criterion of justice formulated in terms of certain *social primary goods*, such as rights, liberties, income, and wealth. Access to these all-purpose means is not only a good proxy for higher-order interest fulfillment, but also much easier to measure than the latter. Measurability is important because the criterion is supposed to be used for public justification: to foster agreement on institutional design decision. Rawls claims that the parties would choose these two principles as the public criterion of social justice (Rawls, 1993, 5f).

> *First Principle:* Each person has an equal claim to a fully adequate scheme of equal basic rights and liberties, which scheme is compatible with the same scheme for all; and in this scheme the equal political liberties, and only those liberties, are to be guaranteed their fair value.
>
> *Second Principle:* Social and economic inequalities are to satisfy two conditions: first, they are to be attached to positions and offices open to all under conditions of fair equality of opportunity [the opportunity principle]; and second, they are to be to the greatest benefit of the least advantaged members of society [the difference principle].

The first principle is to have lexical priority over the second, and, within the second, the opportunity principle is to have lexical priority over the difference principle (Rawls, 1971, 302f). 'Lexical' is short for 'lexicographical' and thus invokes how words are arranged alphabetically, giving priority to the first letter over the second, to the second over the third, and so on. Rawls conceives priorities among principles accordingly: in the comparison of alternative feasible basic structure designs, superiority in terms of a lexically prior principle overrides any inferiority in terms of lexically subordinate ones.

The proposed public criterion of justice requires, then, that a society's basic structure be arranged to secure above all the basic liberties. These include the political liberties, the rights and freedoms included in the rule of law, freedom of thought and liberty of conscience, freedom of association, and the freedom and integrity of the person including freedom of movement and the freedom to hold personal property. Except in the case of the political liberties, the first principle does not require that citizens have sufficient means, such as income and wealth, to take full advantage of their basic liberties; the distribution of such means is governed by the second principle. Yet, the first principle does require more than legal recognition: citizens must have secure access to their freedoms, and attempts to disturb their enjoyment or exercise must be effectively prevented and deterred.

The second principle addresses the social and economic aspects of a basic structure. The opportunity principle requires that persons have roughly equal chances of success irrespective of their initial (childhood) socioeconomic position. The difference principle requires that rules affecting socioeconomic inequalities (such as the tax system and the social safety net) be designed to optimize the lowest socioeconomic position. Existing poverty is justified if, and only if, no institutional reform decreasing or increasing inequality would raise the lowest socioeconomic position.

The Bias toward Purely Recipient-Oriented Theorizing

While Rawls's theory has received much criticism, it has also in the last 40 years shaped the debate about justice and, most

importantly, the dominant concept of justice. There is little awareness now of the distinctive features of, or alternatives to, the specific concept of justice employed by Rawls and his many critics and defenders.

While the word 'just' can, and often does, function as a one-place predicate, the concept of justice, like the concept of mother, essentially involves a second place: to be unjust, a *iudicandum* A must be unjust *to someone*: to certain *recipients* B.

The idea of recipients, of those who have justice claims on a particular *iudicandum*, invokes the question of what their claims on the *iudicandum* are, the question of what these recipients have and do not have, and what they ought to have or not to have. The concept of justice essentially involves, then, also a third place for relevant *goods and ills*, broadly conceived: A is just or unjust to B by affecting whether and to what extent B has C. (As the category of conduct includes omissions, so the category of goods and ills includes the null case of receiving nothing, being denied a good or spared an ill.) For B to suffer an injustice, there must be goods or ills C that B either has-but-should-not-have or lacks-but-should-have.

The concept of justice as explicated thus far – fundamentally a three-place concept, with frequent but derivative one-place and two-place employments – frames current discussions of justice. According to it, justice is a feature of certain *iudicanda*, which depends on their effects on the distribution of certain goods and ills to or among their recipients. One might call this the *passive* concept of justice, because it directs moral attention to those by whom (in)justice is suffered. Employing this passive concept, one will focus on a *iudicandum*'s effects on its recipients – specifically, on its impact on what these recipients are able to have or to be relative to what they ought to be able to have or to be. One will consider a *iudicandum* just in proportion to its impact on the moral quality of the distribution of relevant goods and ills among its recipients: to be just is to promote good distributions. The passive concept thus leads easily to a conception of justice as *distributional*, and much of the current justice literature is indeed about how to code and rank distributions.

This framing of the debate may well be a remnant of long-dominant consequentialist, especially utilitarian, theorizing (Bentham, 1982; Sidgwick, 1981), which Rawls has superficially done so much to displace. The central consequentialist idea is that subjects, conduct, or social rules should be assessed solely by their effects on how well the world goes. Most current theorizing about justice involves the closely related thought that the justice of subjects, conduct, or social rules should be assessed by their effects on the moral quality of the overall distribution of goods and ills among the *iudicandum*'s recipients. In both cases, the interest in outcomes is indirect. How well the world goes is of little practical interest in itself, but can be of great practical interest if one judges the moral quality of other *iudicanda* by their impact on how well the world goes. Similarly, the moral quality of distributions is of little practical interest in itself, but can be of great practical interest if one judges the justice of other *iudicanda* by their impact on the moral quality of distributions.

Does it make sense to take the assessment of distributions as basic and then to judge other *iudicanda* by their distributional effects? With respect to subjects and their conduct, this mode of assessment is widely rejected. Among the timeworn staples of ethics classes are gruesome organ redistribution stories designed to elicit the response that it is often unjust for subjects and conduct to aim at or produce the best overall distributions. Abstractly considered, a situation in which everyone has at least one eye and one kidney is surely morally better than an otherwise similar situation in which some, through no fault of their own, have no functioning eye or kidney while many others have two. But redistributive conduct and subjects aiming at such an abstractly better distribution are nonetheless considered gravely unjust.

With respect to subjects and their conduct, cases of this sort may be used to draw the conclusion that we ought to distinguish between *treating recipients justly* and *promoting a good distribution among them*. The moral significance of this distinction can be illustrated with matched doing/allowing scenarios such as the following. In Scenario One, Art has two functioning kidneys and Sue has none; we must decide whether to give one of Art's kidneys to Sue. In Scenario Two, Art has one functioning kidney and Sue has none; we must decide whether to give a donated kidney to Art or to Sue. (Other things are presumed equal across scenarios, with both Art and Sue urgently wanting the kidney in question.) In terms of their distributional impact, the two decisions are on a par: in each scenario, we decide whether the final distribution of kidneys will be 2:0 or 1:1. A decision in Sue's favor is then in both scenarios equally promoting of a good distribution. Intuitively, however, the scenarios differ dramatically: justice requires a decision for Art in Scenario One and a decision for Sue in Scenario Two.

With respect to social rules, a similar distinction seems called for, and for similar reasons. Just social rules for allocating donated kidneys favor those who, through no fault of their own, have no functioning kidney over those who have one, and thereby promote a better distribution of kidneys. But just social rules do not mandate the forced redistribution of kidneys from those who have two to those who have none, though doing so would also optimize the distribution of kidneys. Once again, treating recipients justly does not boil down to promoting the best distribution. What matters is how social rules *treat* their recipients, not merely how they affect the quality of the distribution among these recipients.

This distinction has been remarkably neglected in current work on social justice. It is not surprising that it plays no role in consequentialist theorizing, which is committed to the view that social rules should be judged by their effects on the overall outcome, irrespective of how they produce these effects. Remarkable is that Rawls's theory, billed as a deontological alternative, likewise makes the justice of social rules depend exclusively on the overall distribution they tend to produce. Rawls assigns no moral relevance to *how* a basic structure design affects the overall distribution of goods and ills. Most of his critics follow him in this.

At least this decision is clearly built into the centerpiece of Rawls's theory: "the persons in the original position try to acknowledge principles which advance their systems of ends as far as possible. They do this by attempting to win for themselves the highest index of primary social goods, since this enables them to promote their conception of the good most effectively whatever it turns out to be. The parties … strive for as high an absolute score as possible" (Rawls, 1971, 144). By

judging alternative social orders in this *purely recipient-oriented* way, Rawls ensures from the start that they are judged exclusively by their 'output' in terms of what overall distributions they generate among their participants – without regard to how they may bring it about that particular social goods or ills end up with particular persons. While Rawls differs from utilitarians in regard to how distributions should be coded and assessed – fulfillment of higher-order interests rather than happiness, and maximin rather than sum ranking or averaging – he shares with them the purely recipient-oriented mode of theorizing about justice.

This approach should lead Rawls to hold that, to be just, social rules must compensate for natural handicaps. It is evident that the extent to which a person's higher-order interests, especially the third, are fulfilled depends not merely on her share of social goods but also on her natural endowments. Someone genetically predisposed toward good health, cheerfulness, intelligence, and good looks is better able to advance her conception of the good than someone genetically predisposed toward sickliness, melancholy, low intelligence, and homely looks. How, if at all, would the parties in the original position take account of this fact? Leaving genetic modifications aside, the parties can formulate a criterion of justice that takes account of the natural distribution by preferring basic structure designs that favor the naturally disfavored in the distribution of social goods (ensuring that no one is very badly off in terms of both natural and social goods) insofar as doing so raises the floor of higher-order interest fulfillment.

Rawls claims nonetheless that his parties would adopt a criterion of justice that assesses each basic structure design solely on the basis of the distribution of *social* primary goods it produces: "a hypothetical initial arrangement in which all the social primary goods are equally distributed … provides a benchmark for judging improvements" (Rawls, 1971, 62). The two principles do not take into account natural primary goods, such as "health and vigor, intelligence and imagination" (*ibid.*). "The natural distribution is neither just nor unjust" (Rawls, 1971, 102).

How might one react to Rawls's apparent inconsistency? First, one might reject and revise his exclusive emphasis on the distribution of *social* goods and ills. In this vein, Amartya Sen (1982, 2009) has argued that, since natural differences among persons evidently influence their quality of life, we should focus on the distribution not of social primary goods but of capabilities. How badly off someone is depends on her access to being well nourished, adequately clothed and sheltered, and so on, which, in turn, depends not merely on her income but also on her physiology as well as the climate and culture she confronts. To this critique, Rawls has responded that he had, for purposes of a first approximation, left severe natural handicaps and disabilities aside and that the remaining natural disadvantages – Sen had mentioned differential caloric and textile needs – are so minor that their accommodation within a criterion of justice is not worth the cost in terms of increased complexity and consequent divisiveness. But this response is unconvincing: even ordinary natural handicaps – such as shortness, poor posture, ugliness, or a tendency toward melancholy and depression – can be quite devastating. And even if severe natural handicaps of mind and body can be left aside in a first approximation, they cannot be ignored in the final version of a theory that real-world citizens are to use as a shared basis for shaping and reforming their society's basic social institutions.

Second, one might defend Rawls by arguing that natural inequalities are of little importance to a person's *true* quality of life: her ability to fulfill her higher-order interests. This response is also unpromising. Innate mental disabilities, resulting in low intelligence or an inability to concentrate, can surely undermine a person's capacity to understand and apply a conception of justice as well as her capacity to form, revise, and rationally pursue a conception of the good. Such disabilities, and genetically based homeliness and melancholy as well, surely also affect profoundly a person's success in advancing her particular conception of the good.

Third, following Rawls's proposed criterion of justice at the expense of his purely recipient-oriented thought experiment for deriving this criterion, one might argue that the distribution of natural goods and ills, however important to persons, is irrelevant to the comparative assessment of basic structure designs, which should be based exclusively on the distribution of *social* goods and ills that each generates. The task of a scheme of social rules is to do justice to, or to treat justly, all those whose lives are regulated by this scheme. This requires a just allocation of the benefits and burdens of social cooperation, not promotion of the best attainable distribution of all social and natural goods and ills that may be relevant to higher-order interest fulfillment or quality of life. Natural inequalities precede social rules, so to speak, as persons already have their genetic endowments and handicaps when they enter society. A justly designed basic structure should not, then, make the naturally favored compensate the naturally disfavored any more than a just parent, administrator, or civil judge should use benefits and burdens under her control to even out natural inequalities. This view faces the difficulty of drawing precisely enough the distinction between social and natural inequalities to which it gives so much moral significance. It is not clear how one can, without considerable arbitrariness, measure the extent to which a given disease or inequality in earning power is due to genetic and to social factors. Taken strictly, this view would moreover lead to the controversial conclusion that there is nothing unjust about a society that has a just economic system but then leaves the allocation of medical care (as well as of the means of mitigating melancholy, homeliness, low native intelligence, etc.) entirely to the market, where those with special disabilities are bound to pay more for insurance.

Toward a More Adequate Theory

A fourth option is to develop a conception of social justice that neither (like Rawls's two principles) ignores natural goods and ills nor (as the original position would suggest) takes account of them on a par with social goods and ills. The key idea is that a criterion of social justice must be sensitive not merely to the intrinsic features of goods and ills (their kind, magnitude, and frequency), which make them relevant to the recipients' quality of life, but also to an extrinsic feature, namely, the *causal pathway* by which social rules affect their distribution. Such a criterion must take account of – and its application thus requires information about – the particular relation between

social rules and human quality of life, which may affect whether some institutionally avoidable shortfall is an injustice at all and, if so, how great an injustice it is.

The intuitive moral significance of this relational feature can be shown by distinguishing, in a preliminary way, six ways in which a social order may affect the goods and ills of its recipients. The following illustration uses six different scenarios, arranged in order of their intuitive moral significance, in which, due to social rules, certain innocent persons are avoidably deprived of some vital nutrients V (e.g., the vitamins contained in fresh fruit). First-class shortfalls are *officially mandated*, paradigmatically by the law: legal restrictions prevent certain persons from buying foodstuffs containing V. Second-class shortfalls arise from *legally authorized* conduct of private subjects: sellers of foodstuffs containing V lawfully refuse to sell to certain persons. Third-class shortfalls are ones that social institutions do not specifically require or authorize but rather *foreseeably and avoidably engender* through conduct they stimulate – as when certain persons, excluded from employment within an ill-conceived economic order, cannot afford to buy foodstuffs containing V. Fourth-class shortfalls arise from private conduct that is *legally prohibited but barely deterred* – as when, emboldened by mild penalties and lax enforcement, sellers of foodstuffs containing V illegally refuse to sell to certain persons. Fifth-class shortfalls arise from *natural factors whose effects social rules avoidably leave unmitigated* – as when certain persons, unable to metabolize V due to a treatable genetic defect, lack access to the treatment that would correct their handicap. Sixth-class shortfalls, finally, arise from *self-caused factors whose effects social rules avoidably leave unmitigated* – as when certain persons, unable to metabolize V due to a treatable self-caused disease (brought on, perhaps, by their maintaining a long-term smoking habit in full knowledge of the medical dangers associated therewith), lack access to the treatment that would correct their ailment.

Even without all necessary qualifications and refinements, this list makes clear that it is highly relevant to the justice of social rules *through what causal pathway* they affect the distribution of goods and ills. It is no truer of social rules than of subjects and conduct that they are just if and insofar as they promote a good distribution.

How can the moral significance of this relational feature be explained? Social rules are not merely imposed *on* people, their *recipients*, but also imposed *by* people. Purely recipient-oriented theorizing ignores these imposers of social rules, and the passive concept of justice has no place for them. Once the assessment of social rules takes account of both recipients and imposers, the sought explanation is at hand: social rules that cause harms by mandating them are more unjust – because they reflect a different attitude on the part of their imposers – than social rules that engender equally frequent and severe harms through overly mild penalties and lax enforcement. The first injustice is close to the negative-duty end of the spectrum (bringing harm about), while the second injustice is closer to the positive-duty end (letting harm happen).

This hypothesis also explains why justice does not require social rules that mandate beatings whenever the total number of beatings is thereby reduced – and why it may (*pace* Rawls, 1971, ch. 4) oppose official restrictions of basic liberties that, by making such liberties generally more secure, enhance citizens' freedom overall. Rawls must count official and private threats to basic liberties on a par: from the prudential perspective of prospective citizens, it is no worse for one's basic liberties to be threatened by laws or government agents than for them to be equally threatened by criminals, terrorists, or drunk drivers (Rawls, 1971, 242). Here Rawls collides with the widely held belief that official violations are morally more significant, so that, for example, a society should not allow its government to restrict or violate the basic liberties of some or all citizens whenever doing so will prevent greater harms to basic liberties by private actors. The mere fact that some 'reform' enhances the safety of the representative citizen on balance is not enough to justify weakening constraints on policing (during a 'war' on drugs or terror) or introducing lower standards of evidence or disproportionate punishments (such as the death penalty for recidivist drunk drivers).

This diagnosis suggests that a genuine alternative to purely recipient-oriented theorizing can be developed by deploying a more active concept of justice, one that includes a fourth essential place for what we might call the *agents* of justice, those who bear or share moral responsibility for the (in)justice of the *iudicandum*. Pursuant to this alternative concept, the injustice of any *iudicandum* presupposes some agent(s), D, responsible for its injustice or for making it more just. Calling this the active concept of justice alludes to its diverting some attention from those who suffer (in)justice to those who produce it.

While the passive concept easily leads to a conception of justice as *distributional*, the active concept suggests a conception of justice as *relational*, involving a relation between particular agents and recipients mediated through a *iudicandum*. By drawing attention to what we owe one another (Scanlon, 1999), to each agent's specific responsibilities for particular *iudicanda* and, through them, to their particular recipients, the active concept leads away from the idea that a concern for the justice of a *iudicandum* is simply a concern for its promoting a good distribution among its recipients. Rather than tie justice to an outcome and thus view it as something that *obtains* to a greater or lesser extent (what would justice be like, and what ought recipients be able to have or to be?), the active concept presents justice as something that *is done* to a greater or lesser extent: by particular agents, through a *iudicandum*, to particular recipients.

To conclude, unjust subjects, conduct, and social rules involve victims unjustly harmed by them. But it does not follow that the magnitude of the injustice is proportional to the magnitude of these harms. The magnitude of the injustice may also vary with how these harms are produced. The active concept of justice invites sensitivity to such relational factors. In regard to social rules, such sensitivity can take the form of a scalar version of the familiar distinction between negative and positive duties. Such a scale is needed to weight the harms that rules produce by how they produce them (mandate, authorize, engender, etc.). A similar such scale is needed to gauge the degree to which different agents contribute to imposing unjust rules. Moral responsibility for the justice of some *iudicanda* may vary from agent to agent. So there may be competition among *iudicanda* – one may have responsibilities with regard to achieving and maintaining the justice of several *iudicanda*, and one may then have to decide how much of an effort one ought to make with regard to each. These issues concerning

responsibilities and their prioritization are crucial for giving justice a determinate role in the real world. And they tend to be overlooked from the start – or grossly oversimplified through a generic duty to promote just *iudicanda* – when the topic is approached in terms of the passive concept of justice.

Abstract

This article discusses the concept of justice from a social psychological perspective. The authors begin by briefly outlining some theoretical precursors of current social psychological research on justice. Another part is devoted to an overview of theories and empirical research in the areas of distributive and procedural justice. The article furthermore addresses interactional justice, why people care about justice, and reactions to injustice in the context of which individual differences in conceptions of justice are briefly discussed. The article ends by discussing some current trends, social applications, and some future challenges in social psychological inquiries of social justice.

The Social Psychological Discussion of Justice

In general terms, justice is assumed to prevail when people get what they are entitled to or deserve on the basis of who they are and/or what they have done. Although relatively clear in abstract terms, to be practically useful this definition needs to be more specific about exactly why, what, and how much particular people are entitled to receive with regard to benefits as well as burdens. Similarly, the basic rule of distributive justice, that people have the right to be equally treated as others who are alike them, leaves unsettled the criteria according to which the likeness of people should be assessed and the kind of treatment that the people should get. Justice can be unambiguously defined only on an abstract level. The abstract definition is, however, open to multiple translations into concrete terms. For that reason, different people or groups frequently disagree in their justice judgments of given conditions or circumstances. Even if views of justice are socially shared, this does not change the basically subjective nature of justice judgments.

In contrast to studies of justice within other scientific disciplines, social psychologists take a descriptive rather than a normative (prescriptive) approach. Their aim is not to stipulate how justice *should* be defined and achieved. Instead, they focus on the subjective sense of (in)justice and its impact on human action and judgment. Thus, social psychologists study what people regard as just and unjust under given circumstances, how people deal with the concept of justice, how they react to situations that they regard as unjust, and under which circumstances, and why, people care about justice.

The subjective nature of justice judgments makes it plausible that people will differ in their assessments of a given situation. Divergent evaluations and interpretations are particularly likely among people who view the situation from different perspectives because they occupy different social positions (Mikula et al., 1998a; Tyler et al., 1997; Walster et al., 1978). The following three perspectives are particularly relevant: the victims (i.e., those who suffer from injustice), the perpetrators (i.e., those who caused injustice), and the observers (i.e., those who witness injustice without being personally affected). Perpetrators typically tend to regard their own behavior as appropriate and just, and they frequently attribute any negative behavior on their part to external circumstances. Victims and observers are more likely to regard the same behavior as unjust and attribute responsibility and blame to the actor (cf Mikula, 1994).

Origins and Early Development of the Field

The social psychological discussion of justice originated from relative deprivation research (Runciman, 1966; Stouffer et al., 1949) and Homans' (1961) propositions about distributive justice. According to Homans (1982) another intellectual root of social justice research is the application of the frustration–aggression principle in social exchange theory. Although in slightly different terms, all these writings proposed that people evaluate outcomes they receive relative to some kind of comparison standard rather than in absolute terms. The comparison standards define the quality of outcome people expect to receive based on the outcomes that other relevant people receive. Thus, the evaluation of a given outcome may vary depending upon the particular comparison standard used. The outcome will be experienced as gratifying and/or just if it is equal to the one received by the comparison standard and unfavorably or favorably unjust if it is lower or higher, respectively. Crosby (1976) suggested that deprivation is related to feelings of resentment, and to feel resentment, five conditions have to be satisfied. The individual who lacks something (X) must (1) perceive that another individual possesses X; (2) have a desire for possessing X; (3) feel entitled to possess X; (4) consider coming into possession of X as feasible; and (5) not feel responsible for lacking X.

Adams' (1965) elaborations (to be described under the next section) refined and extended Homans work and were influenced by Festinger's social comparison (1954) and cognitive dissonance (1957) theories. It should be noted that formulas similar to Adams' had already been proposed by Sayles (1958) and Patchen (1961). These models were initially employed to explain industrial workers' reactions to under- and overpayment at work. Later, Walster et al. (1978) developed equity

theory as a general theory of social justice and applied it to various kinds of social interactions and relationships.

Another important impetus was based on the *just world hypothesis* (Lerner, 1980) according to which people have a basic desire to believe in a just world where people get what they deserve. This desire prompts people to act or engage in cognitive distortion to maintain or reestablish the belief that the world around them is just.

Distributive Justice

Early social psychological conceptualizations of justice focused on one particular form, namely *distributive justice* (i.e., the justice of the distribution of outcomes or resources), as well as on mainly one particular principle of distributive justice, the equity or contribution principle (although equality was intermittently and unsystematically discussed).

An important step in the development of the study of distributive justice was the research and theorizing by Adams (1965) on affective, cognitive, and behavioral consequences of perceived inequity. Like Homans, Adams suggested that people evaluate what they contribute to an interaction or relationship (i.e., their inputs) and what they receive in return (i.e., their outcomes) by comparing the ratio of their own outcomes and inputs with that of others and expect the ratios to be equal. If the outcome–input ratios of a person and the comparison other do not match, people experience inequity. Inequity is an aversive state that motivates people to restore equity either 'actually' by behavioral means or 'psychologically' by cognitive redefinition of the situation. Interestingly, this is assumed to hold equally true for people who are worse off as well as for those who are better off than the comparison other.

The narrow focus of early theory and research on the equity principle was later extended in several respects. Alternative conceptualizations, the multiprinciple approaches, emphasized the existence of several justice norms, in addition to the equity or contribution principle. The equality (to each the same, regardless of inputs) and the need principles (to each according to actual or perceived needs) are two of the most commonly discussed. These approaches assume that different distribution rules are regarded as just and serve as standards of action and evaluation in different circumstances (Deutsch, 1975; Mikula, 1980). For example, the equality principle is assumed to predominate in groups for which solidarity is important, the equity/contribution principle in groups that strive to maximize production, while the need principle is favored by groups that are concerned about the care and nurturing of its members. Empirical studies in this tradition were designed to identify situational and personal conditions that determine which distribution principles are regarded as just and used as a criterion for resource distribution, as well as what positive or negative consequences (regarding work satisfaction, task performance, personal relationships, etc.) will follow from the application or violation of the various principles (Törnblom, 1992).

The various 'main' distributive justice principles may be further specified (or operationalized) into several 'subrules.' For example, the equity/contribution principle may be conceptualized as contributions of effort, accomplishment, or ability; the need principle may be conceived in terms of biological, basic, or functional needs; and equality may be understood as equality of opportunity, treatment, or results. Thus, a specification of a justice principle into the particular subrule that is meant to represent it promotes more conceptual clarity and precision in research, hinders arbitrary practical applications, as well as minimizes the occurrence of communication conflicts (e.g., Kazemi and Törnblom, 2011; Törnblom and Jonsson, 1985).

Procedural Justice

Further developments in the field widened the focus beyond distributive justice and considered additional forms of justice. Justice judgments are frequently made about the decision-making procedures by which the distributions are arrived at as well, that is, procedural justice. The social psychological study of procedural justice was stimulated by the work of Thibaut and Walker (1975). These authors studied people's responses to different third-party procedures of conflict resolution. They found that people regard procedures that provide them with control of the decision-making process (process control or voice) and/or the decision itself (decision control) to be fairer than when either type of control is lacking. In addition, the perceived fairness of the procedures turned out to affect people's satisfaction with their outcomes. Subsequent research studied particular features of the procedures that seemed to contribute to the perception of procedural (in) justice and the consequences of these perceptions (Lind and Tyler, 1988; Tyler et al., 1997).

Justice researchers identified a variety of procedural elements that contribute to the perceived fairness of procedures. For instance, Leventhal (1980) proposed that procedures will be regarded just if they ensure consistent treatment across persons and over time, utilization of accurate information, suppression of personal biases of decision makers, existence of appeal mechanisms by which wrong decisions can be corrected, representation of the affected parties in the decision-making process, and compatibility with fundamental moral and ethical values.

Empirical evidence suggests that people consider procedures that allow them to participate in the decision-making process and express their opinions and views (voice) to be fairer. Interestingly, this seems to occur even when the expressed opinion does not influence the final decision, as long as the respective parties feel that their views have been seriously considered (e.g., Lind et al., 1990).

The perception that the procedures are just has a variety of positive consequences. Procedural justice promotes people's acceptance of decisions, their long-term adherence to agreements, and their willingness to cooperate with groups they belong to. Perceived procedural justice also enhances the perceived legitimacy of civil authorities, institutions and rules, and people's willingness to defer to authorities and their decisions. Finally, perceived procedural justice improves people's satisfaction with the outcomes they receive. Strikingly, these positive consequences result even if the decision procedures lead to unfavorable outcomes for the persons concerned (Tyler et al., 1997).

Interactional Justice

Distributive and procedural justice has received the most attention in the literature. But since the mid-1980s, theory and research have also emphasized the importance of the social and informal aspects of justice in daily encounters (Bies and Moag, 1986; Greenberg, 1993; Mikula et al., 1990). Greenberg (1993) pointed out the importance of considering interactional justice in justice theorizing and distinguished between interpersonal and informational justice as two forms of interactional justice. This has subsequently been supported by Colquitt et al. (2001; see also Colquitt, 2001). There is however some controversy concerning whether or not interactional justice should be subsumed under the broader concept of procedural justice (Bies, 2005; Bobocel and Holmvall, 2001). Procedural and interactional justice may constitute aspects of 'fairness of treatment' (Van den Bos, 2005).

While procedural justice is related to the formal and structural aspects (i.e., rules and policies), interpersonal justice concerns the quality of the relationship or the exchange and social processes taking place between people. Just as distributive and procedural justice is defined in terms of a number of criteria or principles, interpersonal justice is defined in terms of four main criteria: respect, truthfulness, justification, and propriety (Bies and Moag, 1986). Information justice refers to how allocation decisions or enacted procedures are explained to those concerned – the type of information given or how it is given to the individuals. This gives the impression of neutrality and increases people's trust in the authorities. Research on information justice and its effects are very scarce (see Kazemi and Törnblom, 2009).

Why Do People Care About Justice?

The question of why people care about justice received different answers in different social psychological theories. One group of theorists assumes that people are concerned about justice because it serves their interest in maximizing their own outcomes. For instance, equity theorists (Walster et al., 1978) proposed that social systems develop rules of justice, and induce members to follow these rules, because this can maximize collective outcomes. People want to conform to these rules and expect others to do so as long as it serves their self-interest. Lerner and Clayton (2011) recently analyzed existing research relevant to the two motivational forces of justice and self-interest and proposed a model that seeks to integrate them into a comprehensive theory of behavior.

Justice is "conceived as a norm, a value, a virtue, a standard of evaluation of almost any aspect of life and living together, and as a human motive affecting thoughts, emotions, and actions" (Kals and Maes, 2012: p. v). The importance of justice in human social life is related to the fact that justice fulfills four different types of identity maintenance needs: (1) *instrumental* (material identity needs; Thibaut and Walker, 1975; Skitka, 2003), (2) *relational* (social identity needs; Lind and Tyler, 1988; Tyler and Lind, 1992), (3) *protective* (certainty or predictability needs; Lind and Van den Bos, 2002), and (4) *moral* (personal identity needs; Skitka and Mullen, 2002). How justice satisfies each need is briefly described below.

Early theorizing on procedural justice (Thibaut and Walker, 1975) posits that people care about fair procedures, and regard procedures that give them control over outcomes to be fairer, because they help them to maximize their outcomes in the long run. The focus is on the expected and actual outcomes that people receive (i.e., the instrumental perspective). The relational or group-value model of procedural justice (Lind and Tyler, 1988; Tyler and Lind, 1992) provides an alternative perspective. According to this theory, people are concerned about their position in groups. They use previous experiences of how they were treated by authorities as a source of information about their standing or status in the group. Evidence of just treatment is taken as an indicator that they are regarded as valuable and worthy group members that, in turn, has positive implications for their self-esteem and self-worth. Justice judgments are relational in nature and the issues of neutrality, trustworthiness, and status recognition are central to understanding justice. Thus, the relational account holds that people not only have material identity needs, but also need to be treated in a way that makes them feel as respected citizens with certain rights. While providing different explanations of why people care about justice, that is, because of instrumental concerns about outcomes or of relational concerns about group status, both groups of theorists view justice as a means rather than as an end in itself. It seems possible to understand the instrumental and relational models as two sides of the same coin rather than two different coins, that is, the relational model is 'instrumental' as well, as it focuses on obtaining status in the group, while the instrumental model has control as an end. Thus, from that point of view they merely differ in terms of the social resource they see as outcome – instrumentally motivated people seek control and relationally motivated people seek status. Other authors criticize that these views do not capture the essential meaning of justice as a moral ought. Without denying that justice may be used instrumentally as a means to acquire some end or outcome, they argue that justice is inherently an end in itself. People are motivated intrinsically to behave justly, and sometimes act in ways that are irrelevant to self-interest motives and maximization of own outcomes.

According to the protective account, fairness is important as it is conducive to reducing the uncertainty that citizens may experience in their relationships with authorities and fellow citizens. Justice is a norm, and as such functions to coordinate behavior. If I believe in fair play, and expect others to do so, a kind of consensus effect results. Uncertainty management theory (Lind and Van den Bos, 2002) posits that activation of fairness processes is an indication of fairness judgments being utilized to settle some important social or psychological issue. Lind and Van den Bos (2002) suggest that fairness serves people in managing uncertain situations (e.g., are everyone else going to pay his/her taxes?) by giving them "confidence that they will ultimately receive good outcomes and because it makes the possibility of loss less anxiety-provoking" (p. 195).

Finally, the moral account stresses the importance of personal moral standards as an important determinant of how people reason about fairness. For instance, if the individual strongly believes that a mismatch between norms of input (e.g., equitable tax payment) and norms of outcome (e.g., equal or need based access to and utilization of

Medicare and educational services) is immoral and wrong, then s/he tends to perceive the system as unfair regardless of procedural or interactional justice considerations (Skitka and Mullen, 2002).

Reactions to Injustice

Social psychological theory and research distinguished three major types of responses to injustice: (1) cognitive (psychological) restoration of justice by changing the interpretation of the situation, (2) actual restoration of justice by behavioral means, and (3) nonaction or resignation (Adams, 1965; Tyler et al., 1997).

People may prefer cognitive over behavioral reactions to injustice for various reasons. People who caused injustice, and people who are unfairly advantaged, may be inclined to justify the given situation to avoid the need for compensation or restitution and to protect a positive self-image. People who are unfairly disadvantaged may be motivated to deny being victims of injustice to protect their self-esteem, or they may conclude that they are responsible for their own fate. They may also view their negative situation as a result of a legitimate process and thus not regard it as unjust. One's 'moral community' might be redefined, excluding some victims from the rights to be treated justly. Furthermore, moving the focus from one's own situation to that of others,' observers frequently distort others suffered injustices as a result of their own behavior ('blaming the victim,' 'the just world hypothesis').

Behavioral attempts to restore justice include seeking compensation from or retaliating against the responsible agent (sometimes a third party). Examples are disobedience, theft, sabotage, violence, murder, and sick leave. Leaving the unjust relationship is another alternative, even though this option does not restore justice. The likelihood of behavioral reactions of the former type increases when people see a chance of improving the situation, and when they assume that the situation would not change 'by itself.' In addition, anticipated personal benefits and costs may influence the likelihood of behavioral reactions. However, the intensity of experienced injustice seems to be the most important factor. People with strong feelings of injustice are more likely to react behaviorally to injustice regardless of the costs involved and/or the likelihood of success. Behavioral reactions may occur as individual-level responses, collective-level responses or both. Collective reactions are more likely when the injustice is perceived as a collective rather than an individual issue and may be expressed in the form of revolts, strikes, terrorism, war, and the like.

An implicit assumption of equity theory was that a person's inequitable treatment in one relationship will not affect her behavior in other second-partner relationships. In such a case, an additional new inequity would be created. However, studies by Austin and Walster (1974, 1975) suggest that people sometimes try to do so; they focus on equity with the world (i.e., equity across several relationships) rather than person-specific equity. They proposed that individuals are sometimes interested in the amount of net equity they receive across relationships, while at other occasions they may prefer both person-specific equity and equity with the world. Furthermore, Moschetti and Kues (1978) found that transrelational redress by inequitably treated subjects took place in third-partner relationships as well. Some shootings at schools and work places are tragic examples of transrelational equity or equity with the world.

Although fundamental and highly relevant, the daily observation that people sometimes do not react to injustice has not been systematically investigated by researchers in the field (see Törnblom and Kazemi, in press). People may not react to injustice (cognitively or behaviorally) because they feel powerless and have resigned to their fate. Another reason is that people may be afraid of retaliation. This is particularly true in asymmetrical relations (e.g., employer–employee relationship). Finally, they may perceive their situation as normal and appropriate because they compare themselves predominantly with similar others who are also disadvantaged. Sometimes people are even inclined to regard 'what is' as 'what ought to be' (Moore Jr., 1978).

We have already discussed the cognitive and behavioral consequences of injustice but only hinted at subsequent emotional reactions, as broadly conceived by theorists like Homans (1961) and Adams (1965). These theorists proposed that people are likely to experience distributive injustice when individuals in an exchange relationship receive rewards that are seen as disproportional to their investments. People were assumed to react with anger to unfavorable and with guilt to favorable disproportionality. Adams (1965) used the general terms distress and dissatisfaction to indicate that perceived injustice causes aversive affective reactions. Specific examples are stress, dissatisfaction, depression, self-depreciation, feeling of guilt, loss of motivation, and apathy. The connection between emotion and justice is complex and, until recently, a neglected area of theory and research. As noted by several justice researchers (e.g., Hegtvedt, 2006; Mullen, 2007) as emotions are capable of influencing cognitions and evaluations (and behavior), negative affect may very likely precede and result in perceptions of injustice (in addition to the other way around) which, in turn, will lead to additional affective responses (for studies on emotions as reaction to perceived injustice see Clayton, 1992; Mikula et al., 1998b; Sprecher, 1992). Justice judgments (which are cognitive assessments) are assumed to be more time consuming than the less conscious types of emotional reactions which are more immediate and spontaneous.

During the past couple of decades some justice researchers have focused their attention on the importance of *individual* differences in the context of tolerance for or sensitivity to violations of moral norms and injustices (Huseman et al., 1987; Lovas and Wolt, 2002). Two such individual difference constructs related to justice reasoning and reactions to injustice are *belief in a just world* and *justice sensitivity*. Lerner (1980) assumed that people generally believe that the world is a fair place. When this idea is threatened, people usually employ various protective strategies. The conception of the world as a fair (and predictable) place seems more firmly rooted in some people than in others and suggests that people get what they deserve and deserve whatever positive or negative treatments they get. Various measures have been used to tap the construct (see Dalbert, 2001; Lipkus, 1991). Injustices are a major contradiction for individuals who score high on such a scale (i.e., perceive the world as a very fair place). They

are more aversive to injustices, see them as more threatening, and react more strongly than those who see the world as less fair. Justice sensitivity (Schmitt et al., 1995, 2005) is conceived as a dispositional sensitivity to befallen injustice, comprised by four components: frequency (of experiencing yourself as a victim of injustice), intensity of anger (subsequent to unfair distribution or treatment), intrusiveness of thoughts (moral mental load, how much the person dwells on an unfair event), and punitivity (to what extent and in what way you think that an agent of injustice should be forced to restore justice).

Some Areas of Current Interest and Social Applications

Social justice research has expanded to include analyses of several different areas of social life: work organizations, legal institutions, educational settings, civil institutions, social policy and economics, gender issues, other than human species, environmental issues, international conflicts, family issues, close personal relationships, and coping with life crises and victimization. People's perceptions of justice and their reactions to injustice in work organizations have been one of the main areas of social justice research from the very beginnings of equity theory. The rapid growth of this line of research has led some authors to use the generic term 'organizational justice' (Cropanzano and Greenberg, 1997). Empirical evidence shows that the perception of distributive justice affects, for example, work performance, absenteeism, turnover, and people's satisfaction with outcomes they receive. The perception of procedural justice influences workers' organizational citizenship behaviors and reactions to a variety of organizational measures such as personnel selection procedures, performance evaluations, layoff decisions, strategic organizational planning and change, and workplace drug screening.

A full description of an exchange or distribution situation must include information about the object of distribution. What kinds of goods or bads are being distributed, and does the particular type of transferred item affects the process and outcome of the distribution? These types of questions are addressed by *resource theory of social exchange* (Foa, 1971; Foa and Foa, 1974). It features a classification of resources (i.e., any object which is transmitted via interpersonal behavior) into six types: the value of love, status, and services (particularistic resources) is derived from the identity of the provider and his/her relationship to the recipient, which is generally not the case for money, goods, and information (universalistic resources). The exchangeability of these resources (some concrete and some abstract) varies with the personal/social/cultural context within which the resource transaction takes place. The various properties of the resources yield a number of new exchange rules. Resource theory has implications for justice theory in that inappropriate exchanges may generate dissatisfaction and feelings of injustice. Receiving a friendly pat on the back from a customer in return for repairing his car is likely to result in dissatisfaction and arouse feelings of injustice. Furthermore, a given allocation principle may be viewed as just for the distribution of some resources but not for others. Workers usually prefer wages to be paid according to contributions rather than equally to all. The resource features that have most frequently been focused in justice research are their nature, quantity, and valence (i.e., whether the resource is a good or a bad, an asset or a liability, a gain or a loss). Resource theory has stimulated an impressive amount of research – theoretical extensions and integrations (e.g., Markovsky and Berigan, 2012; Törnblom and Vermunt, 2007) as well as empirical research and social applications (for more details see Törnblom and Kazemi, 2012a).

An additional resource issue with implications for justice considerations is the way resources are produced and acquired. Social psychological discussions of distributive justice have focused on resources of consumption to the neglect of the connection between justice and the production of those resources and the access to their means of production. Whether or not a fur coat is genuine or an ornament is made of real or imitation ivory (i.e., produced by murdering animals) will have implications for justice evaluations of exchanges and distributions. The complex linkages between justice and the production, possession, and provision of transacted social resources generate new research avenues (Törnblom and Kazemi, 2007).

Due to the subjective nature of justice, misunderstandings, disagreements, and conflicts between involved parties will easily occur. As Montada (2007: p. 256) points out, "All social conflicts may be interpreted as justice conflicts," and "The aim of conflict settlement is a just peace" (Montada, 2012: p. 15). Relatively scant theoretical as well as empirical attention has been given to this important area of inquiry, perhaps partly due to the imprecise meaning of the umbrella concept of conflict (see Törnblom and Kazemi, 2012b) – for exceptions see Kals and Maes (2012) and Mikula and Wenzel (2000).

Other Areas of Interest and Future Challenges

Frequently individuals and collectives (as well as animals and the environment) are excluded from our moral community. Thus, justice is considered irrelevant and not applicable to some entities in some situations and contexts which, in turn, may lend legitimacy to morally unacceptable treatment and victimization of humans and other animals. Several prominent justice researchers have contributed valuable insights concerning the 'scope of justice' (notably Opotow, 1990, 1993, 1995). A thorough analysis of empirical research within this area of investigation was conducted by Hafer and Olson (2003). As moral behavior and justice are also relevant guidelines in the context of plants and nonliving entities, the threats from global warming, natural resource depletion, and pollution attract much needed research within the area designated as environmental justice (see Clayton and Myers, 2009; Clayton and Opotow, 2003).

Additional areas deserving research attention are intergroup justice, justice versus other competing motives guiding behavior, the proactive usage of justice to promote well being, and theory integration. Further inquiries into the processes in the connection between emotion and justice is another challenging task that would take justice research to the next level (see Cropanzano et al., 2011). These lines of research merely

exemplify the diversity of topics awaiting further theoretical and empirical research (Kazemi and Törnblom, 2008).

Existing social psychological inquiries of justice are to a great extent experimentally oriented; research hypotheses are investigated under controlled conditions. Even though some qualitative studies have been conducted lending ecological validity to experimental results (e.g., Clayton, 1992; Mikula, 1986; Randall and Mueller, 1995), additional qualitative justice research are needed to gain insights into the phenomenology of justice. Also, due to the overrepresentation of research concerned with self-reported behaviors and behavioral intentions, research featuring actual behavior observations is warranted. Furthermore, with the relative rapid accumulation of empirical evidence in the field of justice studies, the need is increasing for theoretical integration, propositional inventories, summaries of research evidence, and meta-analyses. Meta-analyses provide us with effect sizes and assist in identifying boundary conditions and directions in which new research are needed.

Concluding Comments

Some of today's most important global problems are gender inequality, immigration and minority issues, allocation of resources in health care, discrimination, housing segregation, poverty, financial aid, the prevention and resolution of conflict and war, to mention a few. The core of these problems generally boils down to problems of justice. As social psychological research has convincingly shown that people care about justice, and that justice norms and conceptions influence human conduct and thinking, this research may contribute to our understanding and the amelioration of social problems on different levels – the interpersonal, intergroup, organizational, societal, and cultural.

The field of social justice research is very vital, attracting interest of an increasing number of researchers from different disciplines. The dominant social psychological line of research is published in highly ranked international journals such as the *Journal of Personality and Social Psychology*, *Personality and Social Psychology Bulletin*, *European Journal of Social Psychology*, *Personality and Social Psychology Review*, *Journal of Vocational Behavior*, *Journal of Applied Psychology*, *Social Issues, and Social Forces*. *Social Justice Research* (founded in 1987 by Melvin Lerner) is the official journal of the International Society for Justice Research.

Abstract

Since the early twentieth century, most young offender legislation worldwide has been formulated on the basis that children and young people who find themselves in conflict with the law should be dealt with separately from adults and protected from the full weight of the criminal law. These young offender laws are based on an assumption that young people under a certain age are *doli incapax* (deemed incapable of forming the intent to commit a crime) and, accordingly, cannot be held fully responsible for their actions. A commitment to act in a 'child's best interests' and to protect and promote children's human rights are foundational principles for all systems of juvenile justice. A key driver of this phenomenon is the United Nations Convention on the Rights of the Child (UNCRC), formally adopted by the United Nations General Assembly in 1989 and subsequently ratified by 193 countries. Similarly, representative are the authoritative rights-informed guidelines on 'child-friendly justice' that have been ratified by the Council of Europe. A key question, however, is whether and to what extent individual nation-states actually comply with their 'child-friendly justice' obligations. Indeed, there remains a clear disjuncture between the promise of international rights discourse on the one hand and the limitations of territorial jurisdictional implementation on the other.

Universal Human Rights Instruments and Children

The formalization of universal human rights was consolidated with the creation of the United Nations and the adoption of the Universal Declaration of Human Rights in 1948. Subsequently, the United Nations General Assembly adopted five further pivotal human rights treaties: the International Convention on the Elimination of All Forms of Racial Discrimination (1965); the International Covenant on Economic, Social and Cultural Rights (1966); the International Covenant on Civil and Political Rights (1966); the Convention on the Elimination of All Forms of Discrimination against Women (1979); and the Convention Against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment (1984). Each and all of these treaties apply to children, young people, and adults, but it was not until 1989 when the United Nations Convention on the Rights of the Child (UNCRC) was adopted by the United Nations General Assembly, and not until 1990 when the Convention came into force, that a universal human rights instrument focused exclusively and comprehensively on protecting and promoting children's particular interests.

Article 1 of the UNCRC provides that the term 'child' refers to 'every human being below the age of 18 years.' The Convention comprises 54 articles bringing together children's economic, social, cultural, civil, and political rights. General measures incorporated within the UNCRC include a fundamental obligation on governments (referred to as 'States Parties') to develop and sustain a children's human rights infrastructure within their jurisdictional spheres comprising, for example, the right to nondiscrimination (Article 2); the primacy of the child's best interests (Article 3); the right to life and maximum development (Article 6); and the right of children and young people to have their views given due weight in all matters affecting them (Article 12). The UNCRC also provides a range of 'civil rights' including the child's right to freedom of expression and association; the right to receive information; and the right to protection from all forms of violence, abuse, neglect, and mistreatment. The Convention further provides for every child's right to an adequate standard of living and the right to the best possible health care and educational services.

The Universal Declaration of Human Rights (1948), the UNCRC (1989), and each of the intervening human rights instruments have a bearing on juvenile justice law, policy, and practice, be it direct or indirect. Economic, social, and cultural rights; civil and political rights; the elimination of all forms of discrimination; safeguards against torture and other cruel, inhuman or degrading treatment or punishment; protection from violence, abuse, neglect, and mistreatment; a recognition of the 'special status' of childhood; 'best interest' principles; the right to life and maximum development; the right to be informed and the right to be heard, all have salience regarding the treatment of children in conflict with the law. Furthermore, specific and identifiable provisions of these instruments, together with an additional range of more 'specialist' global and European human rights standards, treaties, rules, conventions, and guidelines, relate more explicitly still to juvenile justice.

Human Rights Instruments and Juvenile Justice

International human rights provisions with regard to juvenile justice were initially formulated via three key instruments.

First, the United Nations Standard Minimum Rules for the Administration of Juvenile Justice (the 'Beijing Rules') were adopted by the United Nations General Assembly in 1985. The 'Rules' provide guidance for the protection of children's human rights in the development of separate and specialist juvenile justice systems. They were a direct response to a call made by the 'Sixth United Nations Congress on the Prevention of Crime and the Treatment of Offenders' that convened in 1980. Rule 4.1 provides: "juvenile justice shall be conceived as an integral part of the national development process of each country, within a comprehensive framework of social justice for all juveniles" (United Nations General Assembly, 1985).

Second, the United Nations Guidelines on the Prevention of Delinquency (the 'Riyadh Guidelines') were adopted by the United Nations General Assembly in 1990. The Guidelines are underpinned by diversionary and nonpunitive imperatives: "the successful prevention of juvenile delinquency requires efforts on the part of the entire society to ensure the harmonious development of adolescents" (para. 2); "formal agencies of social control should only be utilized as a means of last resort" (para. 5) and "no child or young person should be subjected to harsh or degrading correction or punishment measures at home, in schools or in any other institutions" (para. 54) (United Nations General Assembly, 1990a).

Third, the United Nations Rules for the Protection of Juveniles Deprived of their Liberty (the 'Havana Rules') were adopted by the United Nations General Assembly in 1990. The 'Rules' center a number of core principles including: deprivation of liberty should be a disposition of 'last resort' and used only 'for the minimum necessary period' and, in cases where children are deprived of their liberty, the principles, procedures, and safeguards provided by international human rights standards, treaties, rules, and conventions must be seen to apply (United Nations General Assembly, 1990b).

Furthermore, the core provisions contained within the 'Beijing Rules,' the 'Riyadh Guidelines,' and the 'Havana Rules' were bolstered, in 1990, when the UNCRC – the most widely ratified human rights instrument in history – came into force. The 'Articles' of the Convention that have most direct bearing on juvenile justice include the following:

- In all actions concerning children … the best interests of the child shall be a primary consideration (Article 3)
- States Parties (governments) should recognize the rights of the child to freedom of association and to freedom of peaceful assembly (Article 15)
- No child shall be subjected to arbitrary or unlawful interference with his or her privacy, family, home, or correspondence (Article 16)
- No child shall be subjected to torture or other cruel, inhuman, or degrading treatment or punishment (Article 37a)
- No child shall be deprived of his or her liberty unlawfully or arbitrarily. The arrest, detention, or imprisonment of a child shall be in conformity with the law and shall be used only as a measure of last resort and for the shortest appropriate period of time (Article 37b)
- Every child deprived of liberty shall be treated with humanity and respect for the inherent dignity of the human person and in a manner that takes into account the needs of persons of his or her age. In particular, every child deprived of liberty shall be separated from adults unless it is considered in the child's best interest not to do so (Article 37c)
- Every child deprived of his or her liberty shall have the right to prompt access to legal and other appropriate assistance, as well as the right to challenge the legality of the deprivation of his or her liberty before a court or other competent, independent and impartial authority, and to a prompt decision on any such action (Article 37d)
- States Parties recognize the right of every child alleged as, accused of, or recognized as having infringed the penal law to be treated in a manner consistent with the promotion of the child's sense of dignity and worth, which reinforces the child's respect for the human rights and fundamental freedoms of others and which takes into account the child's age and the desirability of promoting the child's reintegration and the child's assuming a constructive role in society (Article 40(1))
- States Parties shall seek to promote the establishment of laws, procedures, authorities, and institutions specifically applicable to children alleged as, accused of, or recognized as having infringed the penal law and in particular: (1) The establishment of a minimum age below which children shall be presumed not to have the capacity to infringe the penal law; (2) Whenever appropriate and desirable, measures for dealing with such children without resorting to judicial proceedings, providing that human rights and legal safeguards are fully respected (Article 40(3)) (United Nations General Assembly, 1989).

The United Nations human rights instruments have been further reiterated internationally by the Vienna Guidelines (Office of the United Nations High Commissioner for Human Rights, 1997) and, within the European context, by a movement toward 'child-friendly justice' driven by the Council of Europe. By extending the human rights principles that inform the 'European Rules for Juvenile Offenders Subject to Sanctions or Measures' (Council of Europe, 2009), the Committee of Ministers has formally adopted specific 'Guidelines for Child Friendly Justice' (Council of Europe, 2010). The 'guidelines' echo the UNCRC in stating that "a 'child' means any person under the age of 18 years" (Council of Europe, 2010: Section II(A)) and they apply "to all ways in which children are likely to be, for whatever reason and in whatever capacity, brought into contact with … bodies and services involved in implementing criminal, civil or administrative law" (Council of Europe, 2010: Section I: para. 2). The Council of Europe emphasizes the 'unifying' human rights objective of the 'guidelines' by explaining that they are intended to

> guarantee the respect and the effective implementation of all children's rights at the highest attainable level … giving due consideration to the child's level of maturity and understanding and the circumstances of the case … [Child friendly] justice is accessible, age appropriate, speedy, diligent, adapted to and focused on the needs and rights of the child, respecting the rights of the child.
> (Council of Europe, 2010: Section II(C))

It follows that the European 'guidelines for child-friendly justice' serve to underline many of the provisions of global human rights instruments including: "the minimum age of criminal responsibility should not be too low and should be determined by law"; "alternatives to judicial proceedings … should be encouraged whenever these may best serve the child's best interests"; "respect for children's rights as described in these guidelines and in all relevant legal instruments on the rights of the child should be guaranteed to the same extent in both in-court and out-of-court proceedings" (Council of Europe, 2010: Section IV(B): paras 23–26); and "any form of deprivation of liberty of children should be a measure of last resort and be for the shortest appropriate period of time" (Council of Europe, 2010: Section IV(A): para. 19).

Collectively, therefore, the United Nations and the Council of Europe human rights standards, treaties, rules, conventions,

and guidelines provide what is now a well-established 'unifying framework' for encouraging domestic legislative reform, modeling juvenile justice statutes, formulating policy, and developing practice in all nation-states to which they apply (Goldson and Hughes, 2010; Hamilton, 2011). As such – at face value at least – it might legitimately be argued that the same instruments provide the basis for 'globalized' human rights–compliant and 'child-friendly' juvenile justice. After all, with the notable exceptions of the United States and Somalia, each of the United Nations member states – 193 'States Parties' in total – have formally ratified the UNCRC and committed themselves to its implementation.

Restorative Justice

Key elements in 'acting in a child's best interest' and in the implementation of 'alternatives to judicial processing' have been encapsulated within the notion of restorative justice. Advocates maintain that various forms of conferencing (particularly 'family group conferencing'), sentencing circles, victim–offender mediation, reparation, and restitution provide greater potential to reintegrate the 'offender' back into the community. Both the Council of Europe and the United Nations have offered support for restorative justice and, in the juvenile justice sphere, located it within the context of 'best interests' principles and human rights discourses.

In 2002, the United Nation's Economic and Social Council formulated a number of foundational universal principles relating to restorative justice including noncoercive 'offender' and 'victim' participation, voluntarism, and confidentiality. These principles were integrated within human rights–based procedural safeguards (United Nations, 2002: paras 6–11).

Three years later, the Eleventh United Nations Congress on Crime Prevention and Criminal Justice (United Nations, 2005: p. 3) undertook to 'enhance restorative justice' and urged Member States to recognize the importance of further developing restorative justice policies, procedures, and programs. Similarly, the Council of Europe has recommended that restorative justice approaches should be made available to cover all stages of the juvenile justice process. It further recommends that such approaches should form autonomous mechanisms for conflict resolution and operate independently from conventionally formal means of judicial processing. The Committee of Ministers has stated that:

> Alternatives to judicial proceedings such as mediation, diversion (of judicial mechanisms) and alternative dispute resolution should be encouraged whenever these may best serve the child's best interests. The preliminary use of such alternatives should not be used as an obstacle to the child's access to justice.
> (Council of Europe, 2010: para. 24, our emphasis)

It follows that restorative justice has proliferated globally. Although such proliferation has inevitably given rise to multiple and competing definitions – alongside a diverse breadth of operational practices – the notions of 'reconciliation,' 'redress,' and 'restoration' remain the primary legitimizing logics.

A critical reading of restorative justice raises concerns that its free-ranging and discretionary nature may be at odds with human rights imperatives in the juvenile/youth justice sphere, including principles of proportionality, due process, 'best interests,' and the protection of children in conflict with the law from excessive incursion and unaccountable intervention. Rarely, if ever, do restorative justice approaches replace the conventional apparatus of formal adversarial 'justice'; rather, it is not uncommon for 'restorative' interventions to be reserved for low-level child 'offenders' and/or the readily compliant, while more retributive punitivism is visited upon the 'heavy-enders' and/or the recalcitrant. Rather than serving to replace conventional retributive applications of juvenile justice with 'child friendly' and human rights–compliant variants, restorative justice may serve to facilitate net widening, system expansion, disproportionality, and diversified (but interdependent) technologies of criminalization. In these ways, ostensibly 'informal' and 'restorative' processes might do more to relegitimize rather than challenge formal adversarial systems of juvenile justice (Goldson and Muncie, 2012). It is possible that the 'inclusionary' mechanisms of restoration may allow 'States Parties' to claim adherence to 'best interests' principles and compliance with the UNCRC, while simultaneously accommodating coercive, responsibilizing, and unaccountable interventions on the one hand and failing to disturb the hegemony of retribution and punishment, on the other. This critical reading of the potential of restorative justice suggests its limits in the juvenile justice sphere.

Monitoring Compliance

In order to monitor the translation of the UNCRC into the realm of law, policy, and practice within the national borders of respective States Parties, an international monitoring body has been established. The United Nations Committee on the Rights of the Child comprises 18 democratically elected members drawn from the 193 States Parties. The Committee normally meets three times a year in Geneva, Switzerland, and each of its members is required to act in an independent capacity as distinct from being a 'representative' of their specific country. The Committee has two principal functions: first, to issue 'General Comments' in order to elaborate the means by which the provisions and requirements of the UNCRC should be applied within specific subject domains; second, to periodically investigate the degree to which each State Party is implementing the Convention – and retaining compliance with it – within its corpus of law, policy, and practice. On both counts, the Committee has identified institutionalized obstructions to the implementation of the UNCRC in general and, more specifically, serious breaches and violations of the human rights of children within particular juvenile justice systems.

The 'General Comment' in respect of juvenile justice (United Nations Committee on the Rights of the Child, 2007) emphasizes the principle that jurisdictional systems must seek to safeguard the child's dignity at every point of the justice process and stresses that recourse to judicial proceedings (and especially custodial detention) should only ever be operationalized as measures of last resort. In short, the 'Comment' provides that the primary aims of human rights–compliant

juvenile justice are to meet the child's needs and to protect their best interests. In practice, however, the Committee concludes that implementation of the UNCRC is often piecemeal and that the human rights obligations of States Parties frequently appear as little more than afterthoughts within juvenile justice reform:

> …many States parties still have a long way to go in achieving full compliance with CRC, e.g., in the areas of procedural rights, the development and implementation of measures for dealing with children in conflict with the law without resorting to judicial proceedings and the use of deprivation of liberty only as a measure of last resort … The Committee is equally concerned about the lack of information on the measures that States parties have taken to prevent children from coming into conflict with the law. This may be the result of a lack of a comprehensive policy for the field of juvenile justice. This may also explain why many States parties are providing only very limited statistical data on the treatment of children in conflict with the law.
> (United Nations Committee on the Rights of the Child, 2007: para. 1)

More recently and more significantly, the Committee has detected regressive movement in the form of:

> …a growing tendency in both developed and developing regions of the world to consider — or even reform earlier progressive legislation on juvenile criminal justice — by lowering the age of criminal responsibility and increasing penalties for children found guilty, in a misguided effort to reduce increasing public insecurity and, as a result, weakening the realization of children's rights.
> (United Nations General Assembly, 2012: para. 38)

Concerns regarding piecemeal application or, worse still, regression in the implementation of international human rights standards, stem – at least in part – from the fact that the UNCRC is ultimately permissive and breach attracts no formal sanction. In this sense, Abramson (2006) finds that it may be the most ratified of all international human rights instruments but it also appears to be the most violated, particularly with regard to juvenile justice and that, moreover, such violations occur within a context of relative impunity. While presenting an otherwise positive assessment of the practical impact of the UNCRC in 'transforming the world of children and adolescents,' Abramson (2006) argues that juvenile justice is essentially peripheralized and/or unduly disregarded, even to the point of being 'unwanted.'

Jurisdiction-Specific Noncompliance

Two years after a State Party ratifies the UNCRC, it is obliged to submit an initial report to the United Nations Committee on the Rights of the Child – outlining how it is applying the UNCRC. Following the submission of the initial report, each State Party is required subsequently to provide periodic reports at 5-year intervals. The Committee also considers written evidence submitted by discreet government departments, nongovernmental organizations, national independent human rights institutions (such as Children's Commissioners and Ombudspersons), and children and young people themselves. The principal purpose of such inquiry is to ascertain the extent to which law, policy, and practice within individual nation-states is UNCRC compliant and the degree to which children are treated in accordance with the spirit, if not the word, of the Convention (Kilkelly, 2008; Goldson and Kilkelly, 2013).

With regard to the 'administration of juvenile justice,' the United Nations Committee on the Rights of the Child has repeatedly reported violations of children's human rights. The recurring concerns raised by the Committee particularly relate to Articles 37, 39, and 40 of the UNCRC (see above). Indeed, despite having had over 20 years to move toward full implementation, most states appear to have failed to integrate and embed the Convention within juvenile justice law, policy, and practice. (The Committee's reports on individual countries can be accessed on http://www2.ohchr.org/english/bodies/crc/.) For example, in Western Europe, Austria, Finland, Ireland, Germany, Portugal, Switzerland, and the United Kingdom have each been specifically criticized for failing to separate children from adults in custody and/or for facilitating easier movement between adult and juvenile systems owing to diminishing distinctions between the two (as is characteristic of controversial processes of 'juvenile transfer' or 'juvenile waiver' that allow for the prosecution of children in adult courts in the United States). Similarly, the United Nations Committee report of 2004 on Germany condemned the increasing number of children placed in detention – especially children of foreign origin – including the custodial detention of children with persons up to the age of 25 years. The report on the Netherlands (2004) expressed concern that custody was no longer being used as a last resort, whereas in its report of the same year on France the Committee expressed concern over legislation and practice that tends to favor repressive over educational measures, increases in the numbers of children in prison and the resulting worsening of conditions. The Committee has long been critical of the low age of criminal responsibility adopted in the three UK jurisdictions. It also lists a number of additional concerns with regard to UK jurisdictions, including the inappropriate use of punitive preemptive interventions (such as 'antisocial behavior orders') and the excessive use of custody (Goldson and Muncie, 2006, 2012; Muncie, 2008).

Racialized (In)justice

The persistent recurrence of human rights violations – over time and across space – is compounded by a manifest racialization of juvenile justice practice. Muncie (2008) reported that of 18 Western European jurisdictions studied, 15 were explicitly exposed to critique by the United Nations Committee for negatively discriminating against children from minority ethnic communities and migrant children seeking asylum. The overrepresentation of such children is particularly conspicuous at the polar ends of the system – arrest and penal detention. This especially appears to be the case for the Roma and traveler communities in England and Wales, Finland, France, Germany, Greece, Ireland, Italy, Northern Ireland, Portugal, Scotland, Spain, and Switzerland; for Moroccan and Surinamese children in the Netherlands; and for other North African children in Belgium and Denmark.

Trends across Europe, as elsewhere in the world, appear to indicate that the regulation and governance of 'urban marginality' and poverty is being increasingly prized away from the social welfare apparatus and redefined as 'crime problems' within burgeoning 'penal states' (Wacquant, 2009). Moreover, within such shifts, minority ethnic communities and immigrant groups are bearing the brunt of a 'punitive upsurge' (Wacquant, 2009). In particular, 8 million Roma – the largest minority ethnic group in the European Union – are widely reported as enduring systematic discrimination, harassment, ghettoization, forced eviction, expulsion, and detention. By collating data drawn from 22 country-specific reports, Gauci (2009: p. 6) notes: "most … reports identify the Roma … as being particularly vulnerable to racism and discrimination … in virtually all areas of life." Increased ghettoization of 'foreigner' and Roma communities in various European countries, whether as a result of institutional decisions or practical realities such as chronic unemployment, is serving to consolidate structural exclusion and systematic marginalization: "the creation of spatial segregation and socially excluded localities where communities are effectively denied access to basic services such as water and electricity" (Gauci, 2009: p. 10).

Of course, such phenomena are not restricted to Europe. Cunneen and White (2006) note similar processes of racialized justice in Australia, for example, in particular a persistent overrepresentation of indigenous young people held in juvenile justice detention, despite an apparent favoring of diversion and community-based sentences for other offenders. In the United States, African-American and Hispanic children and young people are markedly overpenalized (Miller, 1996; Acoca, 1999). Indeed, some of the most punitive elements of juvenile justice worldwide appear to be increasingly reserved for, and applied to, children from minority ethnic and/or immigrant populations.

Violence against Children

In February 2003, Paulo Sergio Pinheiro was appointed, at Assistant Secretary-General level, to direct the 'United Nations Secretary-General's Study on Violence Against Children' (the Study). The Study was undertaken in collaboration with the Office of the High Commissioner for Human Rights, the United Nations Children's Fund, and the World Health Organization. It comprises the most wide-ranging and detailed analysis of its type in history. The final report – published and presented to the United Nations General Assembly in November 2006 (Pinheiro, 2006) – concluded that

> Millions of children, particularly boys, spend substantial periods of their lives under the control and supervision of care authorities or justice systems and in institutions such as orphanages, children's homes, care homes, police lock-ups, prisons, juvenile detention facilities and reform schools. These children are at risk of violence from staff and officials responsible for their well-being. Corporal punishment in institutions is not explicitly prohibited in a majority of countries. Overcrowding and squalid conditions, societal stigmatization and discrimination and poorly trained staff, heighten the risk of violence. Effective complaints, monitoring and inspection mechanisms, and adequate government regulation and oversight are frequently absent. Not all perpetrators are held accountable, creating a culture of impunity and tolerance of violence against children.
>
> (Pinheiro, 2006: p. 16)

More specifically, throughout the course of the United Nations Study, a series of 'thematic consultations' – involving leading international experts – convened in order to provide periodic subject-specific reports. In the 'Violence Against Children in Conflict with the Law' report, the Director of the Study observed that "children in conflict with the law … are one of the *most vulnerable* groups to the worst forms of violence" (Pinheiro, 2006: pp. 17–18, emphases added). The juxtaposition of universal human rights discourse and international recognition of state responsibilities to safeguard children on the one hand, and the pervasive violation of children by the States Parties themselves – particularly those in conflict with the law and, more still, child prisoners – on the other is, to say the least, anomalous (Goldson, 2009). Such anomaly echoes Abramson's (2000) earlier analysis of the implementation of the UNCRC within juvenile justice systems in 141 countries that revealed widespread absence of 'sympathetic understanding.' He argued that a complete overhaul of juvenile justice is required in many countries where a range of violations are evident including inadequate or nonexistent training of judges, police, and prison authorities; no (or limited) access to legal assistance, advocacy and/or representation; delayed trials; disproportionate sentences; insufficient respect for the rule of law; incidence of police brutality; and improper use of the juvenile justice system to address other social problems. Particular concerns center on penal detention including failure to develop alternatives to incarceration; overcrowding and poor conditions in custodial facilities; limited prospects of rehabilitation; infrequent contact between child prisoners and their families; lack of separation between child and adult prisoners; inhumane treatment; and, at the extremes, torture (Goldson and Kilkelly, 2013). Beyond this is the question of child execution.

Age of Criminal Responsibility: Corporal Punishment, Life Imprisonment, and Execution

Although there is no categorical international standard regarding the age at which criminal responsibility can reasonably be imputed on a child, the provisions of a number of human rights instruments are pertinent. For example, Article 4(1) of the United Nations Standard Minimum Rules for the Administration of Juvenile Justice (the Beijing Rules) provides: "in those legal systems recognising the concept of the age of criminal responsibility for juveniles, the beginning of that age shall not be fixed at too low an age level." Furthermore, the official commentary on this provision states: "in general there is a close relationship between the notion of responsibility for delinquent or criminal behavior and other social rights and responsibilities (such as marital status, civil majority, etc)." In this way, the Beijing Rules advocate consistency and integrity

within and across the wider corpus of criminal and civil law providing for 'social rights and responsibilities' within a given jurisdiction.

However, the age of criminal responsibility differs widely around the world. In the United States, the minimum age is set at just 6 years (in North Carolina) but most states have set no minimum age at all (Cipriani, 2009). In some Islamic societies, such as Iran, the age of criminal responsibility is linked to the age of maturity or puberty that, according to Sharia law, is 9 years for girls and 15 years for boys. Across the United Kingdom, the minimum ages of criminal responsibility – among the lowest in the European Union – vary from 8 years in Scotland (although from 2010, children under the age of 12 years cannot be prosecuted in a criminal court), to 10 years in England, Wales, and Northern Ireland. Even greater variance is evident across Europe where children up to the age of 14 years (Germany, Italy, and Spain), 15 years (Denmark, Sweden, Norway, and Finland), or 18 years (Belgium and Luxembourg) are deemed to lack full criminal responsibility and, as a result, tend to be processed in civil tribunals rather than criminal courts (Muncie, 2009). Such differences reveal both the extent to which compliance with international standards – regarding the criminalization of children – fluctuates between nation-states and, more problematically, the manner in which some jurisdictions flagrantly flout their human rights obligations. Indeed, from the time of its establishment until February 2009, the Committee on the Rights of the Child has had to recommend, on no less than 65 occasions, that a State Party either increase the minimum age of criminal responsibility or institute a minimum age of criminal responsibility where one did not exist at all (Hamilton, 2011).

The low ages of criminal responsibility that are widely applied in many countries of the world raise serious implications especially with regard to sentences of life imprisonment. In many states in the United States, for example, some offences committed by children have attracted a mandatory minimum sentence of life imprisonment without the possibility of parole. In 2012, the effect of the Supreme Court's ruling that such practices violated the Constitution's prohibition of 'cruel and unusual punishment' was restricted to making the life without parole disposition optional, rather than mandatory (*Miller v. Alabama*, 2012). Furthermore, in 'reviewing the laws of the Commonwealth States with regards to life imprisonment of children' – including 'life imprisonment without parole,' 'life imprisonment with the possibility of parole,' 'detention at the pleasure of the executive or the courts,' and/or 'indefinite detention sentences' – Ratledge (2012) reports that "45 out of 54 Commonwealth States provide for one or more of the types of life imprisonment." Moreover, in at least 40 countries of the world – almost all of which have ratified the UNCRC – children can still be sentenced to whipping, flogging, caning, or amputation and, in at least seven countries, child offenders can lawfully be sentenced to death by lethal injection, hanging, shooting, or stoning (Child Rights Information Network, 2012). At the most extreme end of the continuum of human rights violations, between 1990 and 2011 Amnesty International (2012: n.p.) has documented 87 executions of child offenders in nine countries observing that:

> The use of the death penalty for crimes committed by people younger than 18 is prohibited under international human rights law, yet some countries still execute child offenders. Such executions are few compared to the total number of executions in the world. Their significance goes beyond their number and calls into question the commitment of the executing states to respect international law.

Children's Rights: Contingent and Conditional

The practical translation of universal children's human rights standards and principles is, at least in part, culturally relative. It is also contingent upon social and economic materiality. A persistent problem is how human rights might be equally distributed within a world that is profoundly divided and polarized by social and economic inequalities. The United Nations Children's Fund (UNICEF, 2010) has revealed that even in rich nations, identifiable groups of children are unnecessarily 'left behind,' subjected to poverty, denied access to 'well-being,' and exposed to inequality. Worldwide, more than 1 billion children lack proper nutrition, safe drinking water, decent sanitation, health care services, shelter, and/or education and every day, 28 000 children die from poverty-related causes (Goldson and Muncie, 2006). According to Save the Children UK (2007), children are treated as commodities across all continents in myriad ways including child trafficking, child prostitution, bonded child labor, child slavery, and child soldiers. Whether international bodies and standards of juvenile justice can help in the efforts to bring about much needed changes in conditions, attitudes, and practices remains to be seen.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser—Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Abstract

Kant, Immanuel (1724–1804) German philosopher; academic career at the University of Königsberg. Early interest in natural science led to publications in natural history. Treatise on *First Principles of Metaphysical Cognition* (1755) prefigures the object of Kant's critical philosophy: the conditions of the possibility of human knowledge. 'Metaphysical' is that knowledge which exceeds empirical experience. Kant's transcendental philosophy is professedly a 'metaphysics of metaphysics' in which critical standards for metaphysics are established. Primary condition of human knowledge is the impossibility of knowing 'things-in-themselves'; these are concepts with no access to absolute truth about the world. Our knowledge depends on such concepts, however, and is hence relative, since determined by our cognitive capacities. The *Critique of Pure Reason* (1781) develops these theses systematically. The *Critique of Practical Reason* (1788) draws practical consequences of the first Critique: neither worldly good nor evil, but rather the human will is the foundation of morality. The *Critique of Judgment* (1790) contains theories of aesthetic judgment and of living nature. Kant's political philosophy includes a conception of law, morality, and politics in which human rights guarantee freedom and equality in nation-states bound by international treaty. Kant's powers failed before the completion of his philosophy of nature.

'The character of a true philosopher is such that the philosopher does nothing other than to exercise his natural powers and capacities – this namely through the searching investigation of critique.' This claim cannot be put more humbly – it is the very claim which guided Kant on his way to the *Critique of Pure Reason* and effected a 'revolution in style of thought' which continues until this day. According to Kant, this exercise and development of the best human powers deserves the title of philosophy only then, however, if such activity emanates from independent thinking: 'my philosophy must be grounded in my own self, and not in the understanding of others.' Philosophy cannot merely serve the satisfaction of individual curiosity, but rather should be related to the 'interests of humanity.' At the outset of his critical career, Kant wrote that he would deem himself 'more useless than a common laborer' if he couldn't believe that philosophy would contribute to 'the establishment of the rights of humanity.'

Kant was born on 22 April 1724 in Königsberg into a family of manual laborers of very little means. His schooling took place in the strict spirit of Pietism. At the age of 16, Kant began his studies at the university of his native city, financing himself in part by giving private lessons and playing at the billiard table. The breadth of his subjects of study – mathematics, natural science, theology, philosophy, and Latin – was later to be reflected in the wide spectrum of Kant's fields of inquiry. Initially, his interest in modern physics was particularly strong; he viewed Newton's *Philosophiae naturalis Principia mathematica* as the paradigm of rigorous science.

Kant's first academic publication, *Thoughts on the True Estimation of Living Forces* (1747), owes its importance above all to its central claim, which is very much indicative of Kant's later philosophy. Here the 24-year-old attempts to settle a dispute between Cartesians and Leibnizians by proposing a mediating position relative to the point of view of each party. Kant exclaimed: 'I have already drawn up the path which I would like to follow. I shall set upon it, and ... nothing should prevent me from pursuing it further.' Having lost the basis of his financial support through the death of his father, Kant left the university in 1746 in order to earn a living as private tutor in various families. During this time, Kant had occasion to pursue several extensive studies in natural science, the results of which he published anonymously in 1755 under the title *Universal Natural History and Theory of the Heavens*. Here, both the birth of the cosmos and solar systems, as well as the development of the earth up until the appearance of life and the rational animal, man, is deduced solely from physical laws. In positing the creation of heavenly bodies out of rotating nebula, Kant anticipated Laplace's theory; and the insight that spiral nebula are actually very distant galaxies secured Kant a sure place in the history of astronomy. In the year 1755, Kant returned to the university. Having attained a doctoral degree with a meditation 'On Fire' (*De igne*), he earned his *venia legendi* with a postdoctoral treatise on 'First Principles of Metaphysical Cognition.' In this work Kant marked out that field of problems with which he was to occupy himself for his entire life. Even the so-called 'transcendental philosophy' of the critical period remains connected to the 'first principles,' in that it poses the question after

the 'conditions of the possibility' of our knowledge. Although these 'conditions of possibility' are no longer located in a divine understanding – later, Kant came to understand them as the functional conditions of human understanding and in this respect as *a priori* – they nevertheless continue to be the object of metaphysics.

For Kant, all scientific knowledge is metaphysical insofar as it requires us to go, by means of concepts, beyond purely empirical experience. This is always the case in those passages where Kant speaks of knowledge in general, of 'world' and 'reality,' of morality, beauty, or history. Understood in this sense, transcendental philosophy is a 'metaphysics of metaphysics.' Moses Mendelssohn's famous statement that Kant was a 'Crush-All' of metaphysics should therefore not be so construed, as if all metaphysics had been discredited by critique. Actually, Kant disabled only the claims of a theorational and empirist metaphysics, while setting 'critical' standards which all scientific metaphysics must be able to satisfy.

In the over 25-year period between Kant's postdoctoral thesis of 1755 and the publication of *Critique of Pure Reason* in 1781, Kant wrote several works concerning the foundation of theoretical and practical metaphysics. He also experimented with empirically designed procedures, and began to show a certain affinity for skeptical methods – an affinity which was to prove lasting. Two works from this period give us the impression that Kant might have considered abandoning metaphysics altogether: the elegantly parleying *Observations on the Feeling of the Beautiful and the Sublime* (1764) and the satirical *Dreams of a Spirit-seer* (1766). Kant's appearance of having an antimetaphysical stance must have been strengthened for his contemporaries when, having completed yet another obligatory dissertation 'On the Form and Principles of the Sensible and Intelligible World' (*De mundi sensibilis atque intelligibilis forma et principiis*) in 1770, Kant published nothing worthy of mention for 11 years. In retrospect, we can recognize the approach of critical thought in this second dissertation: space and time are introduced as human forms of intuition which do not belong to things as understanding apprehends them. At this point, however, Kant still thought human understanding capable of a kind of cognition which could apprehend the nature of things as a divine understanding might.

The continuing 'critical' insights of the following years forced Kant to renounce the claim that we are able to know the nature of things. From a human perspective, nothing can be said about how 'things-in-themselves' are constituted. At this point in Kant's philosophical development, such 'things-in-themselves' as a divine understanding might be able to know can no longer serve us as the idea of a substance which could provide a basis for the things we can know. It does not even make sense to pose the question concerning the reality of 'things-in-themselves,' for they are mere concepts – we do not even know if anything corresponds to them. As such, the 'thing-in-itself' is simply an expression of our own limitation. The 'thing-in-itself' may serve as a limiting concept, however, in order to prevent us from deeming human knowledge absolutely certain. Even the pure concepts of understanding and reason do not have access to absolute truth.

Kant by no means contests the possibility of knowledge; he is not an agnostic on this count. Rather, he emphasizes the relativity of human knowledge: every insight, even in the objective natural sciences, is functionally relative to human cognitive capacities. We perceive reality in the manner in which it 'appears' to us. Every objective perception is dependent on the sensible intuition in space and time, and remains in this respect limited to experience. But renouncing experience leads either to analytical judgments, which only express what is already contained in concepts, or it misleads us to speculation, in which all certainty is lost. Yet the speculative thinking of pure reason is not sterile. Under conditions of disciplined self-critique, pure reason may contribute to the guidance and ordering of empirical knowledge (its 'regulative function'), it can ward off dogmatic claims (its 'critical function'), and it can set practical goals in those areas where certain knowledge is not attainable anyway. In this last case, pure reason becomes 'practical reason.'

The *Critique of Pure Reason* (1781), in which Kant systematically developed these insights, initially received little attention. The second edition (1787), elucidated by the Prolegomena (1783) and expanded by the *Grounding for the Metaphysics of Morals* and the *Metaphysical Foundations of Natural Science*, gave rise to a sea change, the likes of which philosophy had seldom seen. Kant's experimental-philosophical proposal for the foundation of the results of human knowledge proceeded no longer from the character of the object, but rather from the conditions of the subject – an innovation which came to be understood as a revolution in science. The 'cardinal propositions' of human knowledge cannot be extracted from 'things-in-themselves,' but rather have their fundaments in our very acts of cognition, and only become the fundament of nature *qua* 'appearance' through human activity. This went very well with the heightened self-confidence of the Enlightenment. The critique of reason declares man originator of his world – without contradicting the results of natural science or questioning the traditional claims of the belief in divine origins. At the same time, the delimitation of knowledge by means of critique serves to assign belief a genuine place. God and world, freedom and the person come to be interpreted as concepts of pure reason; they do not denote any object, but are imperative for the conceptual self-determination of the individual.

This attempt to ground human procedural capacities *a priori* had consequences for practical action; Kant showed these in the *Critique of Practical Reason* (1788). In ethics, too, the cardinal propositions are not grounded in the world, but are the product of our own capacities. It is not possible to speak of any preexisting 'good' or 'evil' in the world: one must seek the origin of these terms solely in the human will. Insofar as this will conceive itself as a rational one, it determines by itself what is to count as morally good. The principle of the will is therefore that of self-determination (autonomy) according to the principle of practical reason in the will itself. So long as we acknowledge a commitment to this principle – and we have already done so when we ask ourselves what we 'should' do – we understand ourselves as free and autonomous. In this way, we have the possibility to orient the principles of our action (maxims) on rational insight and submit them to the general self-jurisdiction of reason, which consists in the categorical

imperative. Like the categorical elements of the perception of nature, the categorical imperative does not emanate from external authority but from man's own conception of himself as a rational being.

No new virtues are made compulsory in Kant's critical refoundation of ethics. Instead, principles from Platonic, Aristotelian, and Stoicist ethics are made subordinate to specific criteria of reason. In the last analysis, the emancipated individual alone must determine these criteria. Justification of behavior through one's own insight (and therefore through one's own reason), which first came into philosophical consciousness through Socrates, ascends to its full conceptual conclusion here. The autonomy of ethical self-determination aspired to since antiquity, while being defined over and against empirical explanation, thereby gains a pointedly individual expression. The 'categorical imperative' has meaning only in relation to the 'maxims' or 'subjective principles' of the individual. It is to be noted that justification always refers only to the 'form' or conceptual part of a moral judgment. The concept alone is meaningless without content or 'material,' however, and this is also the case in ethics.

There are therefore always certain 'preferences' involved in that 'material' which must be adduced to every moral judgment and hence to every moral act. Feelings and passions belong to the moral world. Thus, there must be some feeling which gives impetus to moral action – Kant calls it the 'feeling of reverence.' He is careful not to conflate the necessary motivation of acting with its justification; as in Plato, justification may only proceed from rational insight. Solely by means of this kind of insight can man experience himself as free.

Kant's third critique, the *Critique of Judgment* (1790), contains in Part 1 a grounding of aesthetics, once again departing from human standards alone. Aesthetic judgment is the expression of a harmony of cognitive powers which stimulate the individual pleasurably: whenever sensibility and reason come together and mutually intensify one another, an aesthetic experience is possible. Aesthetic experience also expresses itself in a 'judgment' in which the individual, existing in unrestricted subjectivity, communicates himself to others. Kant frees aesthetic judgment from all claims of scientific truth, moral valuation, and purely sensible satisfaction. In aesthetic experience, everything depends on one's own self-autonomous ('heautonomous') judgment. This faculty of judgment binds all sensible and mental powers together in itself and is capable of producing its own pleasure. What is more, it demands expression among those who are like-minded. Hence the faculty of judgment does not at all isolate the individual, but is the very thing which brings him into a conscious relation with those who are congenial to him.

In Part 2 of the *Critique of Judgment* Kant draws up a theory of living nature. The individual constantly judges nature in analogy to his own experience as an active being. An organism is perceived in accordance with its functional purpose, 'as if' a rational and end-oriented will were operating within it – a will which the individual is admittedly only acquainted with through himself. Kant's theory of the organism attempts to grasp the dynamic complex unity of living beings. In so doing, he draws upon the principle of causation whenever this is possible. In this vein, Kant establishes the definition that the parts of the organism 'join one another in the unity of the Whole by virtue of being mutually the cause and effect of one another's form.' Indeed, a living product of nature stands in itself 'reciprocally as cause and effect.' Kant there by made the way for a theory of 'self-organization' which found much attention in the twentieth century, in biology as well as in physics and sociology. The third critique contains the most important impulses for the following generation of German philosophers, particularly for Schelling and Hegel. These philosophers sought to overcome the subjective limitation of aesthetic and teleological judgments emphasized by Kant within the framework of an extensive objectivity of nature or of mind.

Once he had completed his critical works, the elderly Kant went about the business of drawing systematic consequences for particular areas of research. He only managed this, however, in the domain of practical action. Against the resistance of the Prussian Censor, Kant showed these consequences for religious belief (*Religion Within the Limits of Reason Alone*, 1793) and published in 1796/77 the *Metaphysics of Morals*, containing not only a 'doctrine of virtue' for self-responsible action but also doctrines of law and state. Together with the brief essay *Perpetual Peace*, this work exercised direct influence on the political opinions of Kant's contemporaries.

Kant put the productivity of his principle of critical justification to the test in numerous smaller writings on political philosophy and the philosophy of history, also concerning the concept of mankind or the relation among the sciences. Though he added no new model to the pre-existing political constructions of his time, he did develop a new principle of legitimization for political rule under the auspices of a conception of law and the idea of international treaty. He showed how, under general conditions of law, morality, and politics are connected through the medium of the principle of publicity without being derived from one another. He probably was the first to see that the action of states is not only to be justified with regard to the obligations to its own citizens, but is rather to be measured by 'cosmopolitan' standards which require international protection. Where once was the primarily religiously motivated idea of a Christian and European peace order, Kant placed the concept of an international peace order founded upon legal institutions – a concept upon which was drawn in the foundation of the League of Nations in the twentieth century.

Kant's theory of world peace was an innovation in political theory. It was based upon a historically and economically well-founded diagnosis of the state of mankind on the verge of the complete colonialization of the earth. There is no longer a single political entity on the globe which is independent from the political events in any other given part of the world. Because the surface of the earth offers only limited space, people can no longer make way for one another. War, the historical importance of which Kant recognized, can therefore no longer be a means for political ends. The French Revolution had shown that a people's claim to freedom is capable by itself of causing overdue changes in law. Hence Kant arrived at a comprehensive conception of the right of morality and politics on the basis of 'human rights.' These rights, which guarantee freedom and equality for all, are to be made binding within states by means of a republican and representative constitution, and are to be secured among different states through a system of treaties.

A stop is put to colonial politics by 'world citizens' rights'; at the same time, each individual citizen has the basic right to humane treatment, even in states other than his own. The individual states remain intact as indispensable units of social self-determination, but they are compelled by the dynamics of self-binding law to make internal reforms and to rely upon a federal alliance in their external relations. In his brief treatise on *Perpetual Peace*, Kant sketched a theory of politics appropriate to modern conditions of action through the combination of juridical, moral, rhetorical, and power-political elements.

Kant was prevented from completing his system of natural philosophy by numerous obligations which resulted from the broad public debate over his works. Inspired by the French Revolution, Germany experienced a euphoric decade of critique before the turn of the eighteenth century. Kant was thus exposed not only to a growing following, but also to a rapidly formed and primarily religiously motivated polemic. He gave proof of his literary ability in his equally polemical responses to this polemic. It is an ability which, in Kant's main works of critique, only reveals itself to those who have penetrated the difficult coherence of his thought.

In 1796 Kant ceased to teach and in 1801, at the age of 77, retired. His physical strength, already weak, deteriorated rapidly thereafter. Kant could hardly influence the edition of his lectures on anthropology, pedagogy, logic, and geography which were prepared by his students. Nevertheless, he continued working on the yet incomplete philosophy of nature. In doing so, Kant returned once again to the premises of his epistemological critique and conceived a unity of man and nature which bears a remarkable resemblance to the systems of Schelling and Hegel. While writing, Kant's strength suddenly failed him. The speculative notes break off with increasing regularity, and comments on everyday incidents are interspersed among Kant's notes. These writings, which today are collected and published under the title *Opus postumum*, document the way in which Kant's body gradually failed his mind.

Kant's final years were marked by a deterioration of physical and mental powers which was nevertheless born with dignity. On 12 February 1804, Kant died of old age in his city of birth. Despite numerous offers from other universities, Kant never left Königsberg. Yet he always took an active interest in world events, and kept company with businessmen, administration officials, and officers. He knew the travel literature of his time so well that one might think he had been to Java, America, or London himself. He was an enthusiastic supporter of the ideas of the French Revolution, both in the daily society gathered at his table and in public. In Kant's main œ*uvre* of critique as well as in his wide-ranging biological, social, and political interests, one driving incentive of Kant's philosophy is manifest: the exploration of the possibilities and boundaries of man.

In his lectures on logic Kant often summarized the 'cosmopolitan importance' of philosophy in four central questions: (a) 'What can I know?' (b) 'What should I do?' (c) 'What may I hope for?' (d) 'What is man?' To the first question, Kant added by way of explanation, 'answer *metaphysics*; to the second, *morality* answers; to the third, *religion;* and to the fourth, *anthropology*.' The true meaning of this catalogue of questions is only recognized then when Kant adds that the last question encompasses all the others. In conclusion Kant writes that one could basically count metaphysics, morality, and religion to anthropology, 'since the first three questions are related to the last.' Thus Critical Philosophy appears to be, above all, a comprehensive inventory of the best human faculties – and these are the faculties of reason.

Kantian Ethics and Politics

Abstract

Kantian ethics judges an action as morally good if it is done autonomously out of duty and its maxim could be the foundation of a general law. Neither the purpose nor the outcome of an action have any impact on its moral value. This is why Kantian ethics normally is seen as contrary to any type of consequentialist ethics. But Kant tries to reconcile the human wish for happiness with his concept of morality in his theory of the 'highest good,' and in the Doctrine of Virtues he explains in which sense the outcome of an action does matter. Politics, according to Kant, always has to be strictly under the rule of law as it works to achieve the happiness of the people as an end in itself. Implementing the rule of law also in international politics, Kant hopes that international relations will move slowly toward eternal peace.

In his ethics, Kant pointed out that our ability to follow the moral law as rational beings, that is, our capacity to act freely without being determined by natural inclinations, puts us under the obligation to act out of respect for the moral law according to which we should act so that the maxim of the will could be a universal law. Our own happiness, as a natural end, can never be a moral motive; we may hope only to be rewarded for our efforts in eternal life. Nevertheless, we ought to take care of our own well-being because this makes it easier for us to act morally, and in his treatment of different virtues and vices, Kant put a great deal of emphasis on self-respect. Politics, according to Kant, always has to be under the rule of law. Although Kant admited that the aim of politics is the happiness of the people, he insisted that this must never be contrary to the principles of law, which he defined as the compatibility of one person's outer freedom with the freedom of all others. In international politics, Kant postulated a federation of free states that – he hoped – would move slowly toward eternal peace.

Kantian ethics judges an action as morally good if it is done autonomously out of duty and its maxim could be the foundation of a general law. Neither the purpose nor the outcome of an action have any impact on its moral value. This is why Kantian ethics normally is seen as contrary to any type of consequentialist ethics. Politics, according to Kant, always has to be strictly under the rule of law as it works to achieve the happiness of the people as an end in itself. Implementing the rule of law in international politics as well, Kant hoped that international relations would move slowly toward eternal peace. (Because it is not in all cases clear whether Kant meant 'right' or 'law,' and because he sometimes seemed to make use of the double meaning of the German word *Recht*, it is more appropriate to use the word 'right' instead of 'law,' as Mary Gregor did in her translation; Kant, 1996.)

Kant drew a clear distinction between the fields of morality and legality. Hence, it is possible to discuss these topics separately, without denying the important connections that are due to the common origin of their key principles in (practical) reason while the nature of these connections is still under debate. (cf, e.g., Kersting, 1993: pp. 175ff.; Flikschuh, 2010: pp. 62ff.; Guyer, 2002; Willaschek, 2002)

Ethics of Duty – Ethics of Autonomy

Although, as with any other label, it is an oversimplification to reduce Kantian ethics either to an ethics of autonomy or to a mere ethics of duty, it might help to find an initial approach to say that somehow it is both (Baum, 2005). The connection between these two central concepts will be clarified later. They both signify, however, that Kant did not develop a eudaimonian (happiness-based) or any type of consequentialist ethics. Kant did not think that happiness is unimportant for human life; to the contrary, to pursue one's happiness is a moral duty (Himmelmann, 2003; Allison, 2011). But he deliberately rejected ancient eudaimonian ethics as a possible foundation for morality, and centered his postcritical works on moral philosophy around the concepts of duty, autonomy, and moral law (Wood, 1999; Timmermann, 2009; Forschner, 1993; Wike, 1994). Simplifying again, it seems helpful to characterize Kantian ethics within three steps, more or less identifying each with one of the central Kantian works on moral philosophy.

Extracting and Vindicating the Categorical Imperative: The Groundwork of the Metaphysics of Morals

In his first larger postcritical work on ethics, starting from the statement that nothing can be called good without restrictions except a good will, Kant showed that a will is good if and only if it acts autonomously out of duty and according to the categorical imperative (CI). Everything other than a good will may be used with bad intentions. Even some of the virtues can be held by immoral people as the "coolness of a scoundrel" proves to us (Kant, 1996: p. 50). By saying that lack of success does not diminish the moral value of good will "as something that has its full worth in itself" *as long as good will acts "with its greatest efforts"* (Kant, 1996: p. 50), Kant immediately answered some of the most tenacious objections to his ethics.

The main topic of the groundwork of the metaphysics of morals (GMM) is an attempt to clarify the relations between duty, autonomy, and the law of morals. First, Kant showed that the concept of duty is the best way to explain what is meant by a good will; particularly, how the moral worth of an action does not lie in its expected effect but in the principle of volition. An action is morally good if it is not only done in *conformity*

with duty but *from duty* (Kant, 1996: p. 53). Duty is defined as "the necessity of an action from respect for law" (Kant, 1996: p. 55) (according to the principle that I ought to act in such a way that my maxim could become a universal law) and respect is defined as a feeling that is "not received by means of influence" but "self-wrought by means of a rational concept and therefore specifically different from all feelings … that can be reduced to inclination or fear" (Kant, 1996: p. 56). In Kant's view, the question of whether our maxims could become a universal law provides us, "inexperienced in the course of the world" as we are, with an easy test of whether the maxim of our volition is morally good. This is what "common human reason" has "always before its eyes and uses as the norm for its appraisals," although it "admittedly does not think so abstractly in a universal form" (Kant, 1996: p. 58). It is important to notice Kant's regard for common human reason and the morality of the common people, which is, according to his own testimony, due to the influence of Rousseau (Schneewind, 1998: pp. 487ff.; Kant, 1902: ff. XX, 44). Kant did not see the CI "act only in accordance with that maxim through which you can at the same time will that it become a universal law" (Kant, 1996: p. 73), as an invention of philosophers, but rather he saw it as a precise and short formula of how ordinary people think about morality. What he claimed, however, was that – until now – no philosopher had found a clear and precise description of what common reason thinks about ethics.

Nevertheless, common human reason might indeed find some difficulties in the abstractness of this account, just as philosophers have until now. This can be seen from the comment of Friedrich Schiller who felt immoral because he loved his friends from inclination and not from duty. Hence, it should be mentioned that actions in conformity with duty that are motivated by inclination are not immoral. We just have no means to judge whether they are moral. Kant, however, distrusted inclination, which he characterized in the *Critique of Practical Reason* (*CPrR*) as "blind and servile, whether it is kindly or not" (Kant, 1996: p. 235).

On the other hand, as Kant explained from the outset of the second part of his *Groundwork*, we never really know whether we, or anybody else, acts from duty. If we look closely enough at all empirical actions, even at those "from love of humankind" that are generally in conformity with duty, we "come upon the dear self, which is always turning up" (Kant, 1996: p. 62). Therefore, we require an "isolated metaphysics of morals" that is made for all rational beings. Thus, there are the two results: (1) that morality is something for rational beings and (2) that a will is a good will not from love of mankind or any other inclination but from its accordance with the moral law. With good will reason itself becomes practical.

An ongoing subject that is discussed several times in this and in the later works is the relation of happiness to morality (Hills, 2009). Kant constantly argued that morality cannot be based on any principle about happiness. He had different reasons for saying this. First, because instinct is a much better guide to happiness than reason, it would have been an unnecessary and useless effort of nature to provide us with reason if it were for the sake of happiness. Although this argument has been criticized for its obscure 'naturalism,' one may in fact agree with the view that happiness is a natural aim for rational beings, so it is useless to set the pursuit of happiness as a norm. According to another argument "it is a misfortune that the concept of fortune is such an indeterminate concept that, although every human being wishes to attain this, he can still never say determinately and consistently with himself what he really wishes and wills" (Kant, 1996: p. 70). Furthermore, because it is difficult to predict the result of an action, it would be difficult to decide whether it is right or wrong, whereas, in Kant's view, it is very easy to know how the categorical imperative handles this. However, it is important to notice that morality and happiness are by no means necessarily in conflict. They are just logically independent, insofar as happiness is the most general term for an object of the will, that is, for the matter of the will, while the will's moral goodness is due to its form (*CPrR*, Kant, 1996: p. 160). It is even a moral duty to preserve one's own happiness just to avoid the temptation to act immorally out of poverty or envy.

The rejection of happiness as the basic moral end in itself leads Kant to the characterization of the CI as the one and only unconditionally valid imperative. In contrast to the imperatives of skill and prudence (prudence teaches us how to achieve happiness), there is no external end that justifies the categorical imperative. Another result is the special status of *rational* beings as ends in themselves. Kant's hypothetical construction of a 'kingdom of ends' (*Reich der Zwecke*), which is somehow included in the concept of every rational being, may be the best tool to show how closely duty, autonomy, and the moral law are interrelated in his moral philosophy. In the kingdom of ends, every rational being, including God, that is, every person, is seen as a lawgiver of the moral law. This is the reason why they are autonomous. Every finite rational being has the duty to follow this law. Every rational being is an end in itself and thus benefits from the moral law. Because of its deeply egalitarian character, obviously influenced by the Rousseauian view of the *volonté générale*, it might be better to follow Mary Gregor's suggestion for an alternative translation of *Reich der Zwecke* by "commonwealth of ends" (Kant, 1996: p. 83, on the "moral force of reciprocity," cf Korsgaard, 1996: pp. 194f.). In the discussion over the past few decades on animal and medical ethics, the question has been raised whether the circle of those who benefit from the moral law should be expanded to include beings that are not rational or only potentially rational (Nussbaum, 2006; Potter, 2005).

Because of the inordinate reliance on the *Groundwork* in the attempt to clarify Kant's moral philosophy, the charges of formality and emptiness have been laid against Kant. An integral reading of his works shows, however, that this charge is misplaced. It even becomes clear that it would be misleading to label Kant a 'rule ethicist.' True, maxims can be tested as to their universality, but on the ground of maxims alone it is not always possible to decide what to do in a particular situation. Kant was perfectly aware of this, as his stressing of the importance of the faculty of practical judgment and his casuistic questions in the *Doctrine of Virtue (DV) of the Metaphysics of Morals* make clear. Before we deal with these issues, we must look at why the CI is valid or why we should be moral, in Kant's words, how the categorical imperative is possible (cf Guyer, 1998). Although

Kant's main thrust on this issue is found in the *CPrR*, it is worth seeing how he dealt with the question in the *Groundwork*.

The Moral Law, Free Will, and the Highest Good: The Critique of Practical Reason

In the third part of the *Groundwork* that points to a critique of pure practical reason, Kant posed the following question: "But why, then, ought I to subject myself to this principle and do so simply as a rational being, thus also subjecting to it all other beings endowed with reason?" (Kant, 1996: p. 96). Here he answered this question by removing a "kind of circle" (Kant, 1996: p. 97, Schönecker, 1998). It seems that, on the one hand, we must be free from causal determination to be subject to the moral law, and on the other hand, we must declare that we are subject to the moral law because we are free. Freedom (i.e., autonomy), however, consists of the self-constraint of the will through the moral law.

Kant found his solution by making the distinction between two 'standpoints.' In one, we are in the world of senses, having only cognition of appearances, never cognition of things in themselves. In the other, we are, especially in a practical context, members of the world of understanding (Kant, 1996: p. 98). However, "as a rational being, and thus as a being belonging to the intelligible world, the human being can never think of the causality of his own will otherwise than under the idea of freedom" (Kant, 1996: p. 99), and this means submitting to the moral law. This being said, Kant admitted that we can never explain *how* pure reason becomes practical (Kant, 1996: p. 104). This seems to be the problem of his moral philosophy in general: The 'good will' through which pure reason becomes practical is in the intelligible world of understanding. Then it is difficult to understand how it can be *my* will. Or it is *my* will, and then it is difficult to see how it can be separated completely from all my emotional attitudes. In its essence, this problem remains more or less the same from the GMM until the *Metaphysics of Morals* (Timmermann, 2009; Engstrom, 2010). Even if we say that in accordance with the principle of charity we should read these passages in the sense that both parts are the result of abstraction from the 'disturbing' elements of the other side, it is Kant himself who has driven these abstractions to their extreme. To talk of two standpoints does not help much while there can be no explanation of their interrelationship.

The connection between the freedom of will and the rule of the moral law – the first is what makes the law hold, the second is what makes freedom known to us (*CPrR*, Kant, 1996: p. 140) – is one of the main topics of the *CPrR* in which Kant maintained several times that, with moral law, we have in practical contexts as a reality what could in theoretical philosophy only be proved to be not impossible in the solution of his 'third antinomy' in the *Critique of Pure Reason* (Kant, 1902: ff. III, 366ff.; cf Wood, 1999: pp. 172ff.; Ertl, 1998).

In a comment in section 7 of the chapter on the principles of pure practical reason, Kant explained the fundamental law of pure practical reason, that is, the CI, as a "fact of pure reason" (Kant, 1996: pp. 164f.) that is not empirically found. It is not quite clear what is meant by this cryptic formula, which is repeated several times within the *CPrR* and other Kantian works, sometimes with slight variations and has been criticized as well as defended (Kleingeld, 2010). But it appears not to mean that something is revealed to pure reason or to us by pure reason but rather that the use of pure reason in practical contexts implies that we are under obligation by moral law.

Happiness is the natural object of desire of human beings, that is, of all rational and finite beings, whereas the moral law rules the formal structure of the will, happiness, like any other material content, cannot be the incentive for moral law. Kant explicitly rejected the moral relevance of any distinction between higher and lower pleasures. Nevertheless, Kant tried to reconcile the human wish for happiness with his concept of morality in his theory of the 'highest good,' where he found in the doctrine of Christianity – in contrast to the teachings of the Epicureans and the Stoics (Kant, 1996: pp. 241ff.) – a chance to give to those who are worthy of happiness the "hope of some day participating in happiness to the degree that we have been intent upon not being unworthy of it" (Kant, 1996: p. 244). To support this hope, he proposed in his doctrine of postulates not only the freedom of will but also the immortality of our soul that continues its way toward perfection even after our death and the existence of an almighty god who can and will give deserved rewards to those who lived in conformity with moral law. Perhaps one cannot be sure that a *postulated* god can give *real* hope to everybody and an incentive to follow the moral law. Perhaps, instead, some may find this incentive in the hope for glory or in the hope to contribute to the moral improvement of the world or in something similar.

Living the Categorical Imperative: *The Doctrine of Virtues*

In the *DV* of his late masterpiece the *Metaphysics of Morals*, Kant dealt with the different types of duties that cannot be ruled by outer laws – duties of man concerning himself and his perfection and duties concerning the happiness of others. In the *DV*, it becomes clear that for Kant there are obligatory ends for human beings: This indicates that his moral philosophy, which surely is not a variation of consequentialism, is not a pure *Gesinnungsethik* either, that is, the outcome of an action does matter, although it is not always in our hands what this outcome might be (Herman, 2011). To be sure, that does not mean that the moral quality of an action is determined by anything else other than the quality of the motivation and the universality of the maxim in question. This includes the idea, however, that the agent must do everything he or she can to make morality (in the form of moral actions) a reality in the world. Because we have a duty to follow the CI, we have a duty to pursue our own perfection and the happiness of others. We also have duties toward ourselves. These are, again, due to our 'double existence' in the world of appearances and the intelligible world. We have duties toward ourselves as rational beings, that is, toward the humanity in us (section 3, Kant, 1996: p. 544).

A second important achievement of the *DV* compared with earlier works is the casuistic element that demonstrates how Kant's ethics might be applied, at least in some cases. There are also considerations on the use of judgment (*Urteilskraft*) in the *CPrR* (Kant, 1996: pp. 194ff.). But here, "the rule of judgment under laws or pure practical reason is this: ask yourself whether, if the action you propose were to take part, you could indeed regard it as possible through your will" (*CPrR*,

Kant, 1996: p. 196, on moral judgment see Herman, 1993). In his later work, however, Kant used the humanity formula, that is, our duty to respect the moral law and our duty to respect the humanity in ourselves as well as every man as an end in itself to deal with particular subjects. Among these questions and subjects are suicide – that is, to be seen as "debasing humanity in one's person" and therefore morally forbidden (section 6, Kant, 1996: p. 546), as well as "defiling oneself by lust" (Kant, 1996: pp. 548ff.), avarice (Kant, 1996: pp. 555ff.), and servility – "self-esteem is a duty of the human being to himself" (section 11, Kant, 1996: p. 558) – as well as also duties like beneficence and gratitude (Kant, 1996: pp. 571ff.) and vices like envy and malice (Kant, 1996: pp. 576ff.). Kant also dealt with friendship (Kant, 1996: pp. 584ff.). Particularly in the 'casuistic questions' that are added in different places, one can find that Kant's views on these subjects were somehow strict. They are more diversified than might be expected after reading the *Groundwork* and even the *CPrR*. Nevertheless, a remaining problem appears to be that Kant supplied no guidelines on how to interpret the moral law in 'hard cases,' although it might be said that this cannot be the task of virtue ethics in Kant's understanding (Esser, 2004: p. 267). This partly is due to his view that a law court, which he often used as a metaphor for the internal judgment of the conscience (*DV* section 13, Kant, 1996: p. 560), must *apply* the law via imputation, not *interpret* it – that is, the court has to decide whether this individual case falls under the law, not to explain what the law means. This seems to have been a common view of eighteenth-century continental legal theory. On the other hand, Kant may be the first philosopher who recognized that to apply a rule we need a faculty of its own, which he called the faculty of judgment (Esser, 2004: pp. 258ff.), a discovery that is sometimes attributed to Wittgenstein's reflections in rule-following.

Right and Politics

According to Kant, any ethically acceptable politics has to take place under the rule of right. It is the duty of 'moral politicians' who are opposed to hypocritical 'political moralists' to do their best to bring constitutions of states and political relations between states "into conformity with natural right, which stands before us as a model in the idea of reason" (Toward Perpetual Peace, TPP, Kant, 1996: p. 340). Nevertheless, there is an aim of politics on its own, that is, the happiness of the citizen (TPP, Kant, 1996: p. 351) – something that might be surprising to some of Kant's critics. Therefore, pivotal to Kant's legal and political philosophy is, first, his treatment of right and how to determine its realm and, second, his hope on historical development toward peace and republican government. The key engine for bringing about legal progress is the public use of reason (Toward Perpetual Peace, TPP, Kant, 1996: p. 351).

Right as Compatibility of Freedom

Defining right in the *Introduction to the Doctrine of Right* (*DR*) of his *Metaphysics of Morals* as the condition for the compatibility of one person's outer freedom with that of the other (Kant, 1996: p. 387), Kant gave an account of every human being's innate right of freedom as "independence from being constrained by any other's choice" (Kant, 1996: p. 393). In fact, according to Kant, "right is connected with an authorization to use coercion" (Kant, 1996: p. 388) as long as this coercion is opposed to a wrongful "hindrance to freedom in accordance with universal laws" and so is understood as "a hindering of a hindrance to freedom" (Kant, 1996: p. 388). 'Strict right' that is "not mingled with anything ethical" can even "be represented as the possibility of a fully reciprocal use of coercion that is consistent with everyone's freedom in accordance with universal laws" (Kant, 1996: pp. 388f.). The strict reciprocity of rightful coercion shows how crucial the egalitarian element is in Kant's legal philosophy, together with the emphasis on freedom from any other's arbitrary coercion.

Kant's *Doctrine of Right* begins with private right "concerning what is externally mine or yours in general." According to Kant's view, individual possession already exists in the state of nature (section 9, Kant, 1996: pp. 409f.) because the earth, which is originally in common possession, has to be divided according to the "originally united will," which is in accordance with the postulate of pure practical reason that there can be no res nullius (Byrd and Hruschka, 2010: pp. 132ff.). There have been vehement discussions about whether this view together with the general fact that private right is treated before public right justify looking at Kant as a possessive individualist (Saage, 1994; Zotta, 2000) and whether Kant's statement that this possession is only provisional and 'conclusive possession' is possible "only on a law of a common will" (section 9, Kant, 1996: p. 410) means that the common will just confirms possessions won in the state of nature or whether it rearranges and redistributes possession according to principles of justice, such that Rousseauian and therefore egalitarian parts would gain more weight. Kant rejected Locke's founding of property on work, because work is something 'accidental' to the land that cannot decide whose property it is (sections 15 and 17) and because it bases provisional possession on first occupation and conclusive possession on the common will (cf Williams, 1983: p. 94; cf Kersting, 1993: pp. 337ff.). Perhaps one might say that although Kant's primary concern is with individual freedom, which implies appropriation in the state of nature – according to his definition of right – he nevertheless has a sense of public welfare and distributive justice because freedom is not a privilege, but rather it is a universal right (Rosen, 1993; Westphal, 2002; Kaufmann, 2005; Ripstein, 2009: pp. 267ff.).

Because in the state of nature, property and any right are insecure "however well disposed … human beings may be" (section 44, Kant, 1996: p. 456), we have the moral and legal duty to enter a state of public right (section 42). What Kant described in his *DR* is 'the state in idea' that "serves as a norm for every actual union into a commonwealth" (section 45, Kant, 1996: p. 457). Kant clearly preferred a republic with division of powers that is the only alternative to despotism and "any true republic is and can only be a system representing the people" (DR section 52, Kant, 1996: p. 481), which is obviously incompatible with the absolutist and feudalist systems of his times. Therefore, there is another discussion on whether he really rejects every resistance against unjust regimes so bluntly as it looks like in the published

works (DR section 49 A, Kant, 1996: pp. 463f.; OCS, Kant, 1996: p. 303) or whether there might be some more or less hidden hints that he sees it in a more nuanced manner (Beck, 1993; Westphal, 1992). Anyway, it seems to be clear that Kant prefers reform of the constitution (Goyard-Fabre, 1996: pp. 217f.) and for this he claims again and again the transcendental principle of publicity and of freedom of the pen (OCS, Kant, 1996: p. 302).

According to an interesting and attractive interpretation, Kant accepted the political systems of his time – and perhaps he would do the same with those of our time – mainly because they provide us with the possibility of a change toward more just societies that are closer to the state in the idea (Brandt, 1982; Kersting, 1993). But this change has to be done by the sovereign via reform and not by the people via revolution (DR section 49 A, Kant, 1996: p. 465). As we have to accept the state of affairs in the distribution of property at least provisionally for being able to enter a civil state with distributive justice (DR section 41), we have to accept the actually existing legality for being able to transform it by rightful means until it comes close to a true republic. On an international level, we have to accept large parts of the actual distribution of power for being able to approach eternal peace via a commonwealth of free republics. The common tool for this treatment of nonperfect social situations is the permissive law that allows us to live in circumstances that are contrary to the principles of right as long as a quick change by means of right is impossible and as long as there is a serious effort to improve the state of affairs. Since Kant's use of the term 'permissive law' in different places is rather complicated (Hruschka, 2004; Byrd and Hruschka, 2010: pp. 94ff.) and at the same time not that independent from the natural law tradition as sometimes suggested, there have been intense debates about this interpretation, which nevertheless has not been discarded on the whole (Kaufmann, 2005).

Toward Perpetual Peace

One of the most influential and effective elements in Kant's political philosophy might be his proposal of an international legal order that could be able to guarantee eternal peace that is 'a suspension of hostilities' (TPP, Kant, 1996: p. 317). There had been considerations how to realize a peaceful world through a council of the sovereigns like the *Projet pour rendre la paix perpétuelle en Europe* of the Abbé St Pierre. What Kant did – again under the influence of Rousseau – is to connect the international order with the inner structure of the state. His first 'definitive article for perpetual peace' therefore says that "the civil constitution of every state shall be republican" (TPP, Kant, 1996: p. 322) and the second that "the right of nations shall be based on a federalism of free states" (Kant, 1996: p. 325). This 'surrogate' for a world republic – which seems to be unachievable under current conditions – provides a way to maintain the sovereignty of the participating states with the rule of right, the only alternative to the unacceptable rule of war, "right cannot be decided by war and its favorable outcome" (Kant, 1996: pp. 327f.).

On the other hand, Kant is not a categorical pacifist. He accepts that wars had played an important role in the development of mankind (*Idee zu einer allgemeinen Geschichte in weltbürgerlicher Absicht*, Kant, 1902: ff., VIII, 24ff.), and he would prefer the warlike state of nature to a repressive world monarchy (TPP, Kant, 1996: p. 336). He is not an unrealistic dreamer who expects world peace within a short time. Anyway, as Doyle (Doyle, 1986) and others have shown, it was not an unrealistic assumption that democratically governed states tend to demonstrate much less bellicose behavior toward each other than other forms of government. Kant rather thought, or hoped, that with the help of the "great artist nature" (*die große Künstlerin Natur*, TPP, Kant, 1996: p. 331), human societies would move slowly but steadily toward the federation of free republics guaranteeing eternal peace. Kant's idea seems to be that even immoral actions ultimately lead to an improvement of the legal order without discharging the culprit of his responsibility. Somehow behind the back of the agents who are looking for their personal advantage, the artist nature works in a way like Smith's 'invisible hand' toward this federalism of republics that might even turn into a world republic. Anyway, this historical development prepares conditions under which persons may act morally much more easily than it is for them now in a situation that is closer to the state of nature.

Kant did not consider this "mechanism of nature" (TPP, Kant, 1996: p. 331.) as a natural law. Rather it is a projection of practical reason, a hope we must have because we have a duty to move toward eternal peace. Elsewhere, Kant said, "if we can't prove that a development will take place but can't prove the contrary either, a need of reason (*Vernunftbedürfnis*) gives us the right to expect what seems more rational" (Kant, 1902: ff., VIII, Kleingeld, 1995: p. 94).

Abstract

Valdimir Orlando Key, Jr. was a major figure in the development of modern empirical analysis of American political parties and electoral politics. Among his noteworthy contributions were (1) a comprehensive, magisterial analysis of Southern politics in the USA during its apartheid era shortly before that was brought to an end. The methodology employed involved a combination of 'thick description' based on interviews and other sources in each of the eleven states under study, as well as imaginative graphic use of aggregate electoral data. Key's analysis of the region's influence on national policymaking was a significant contribution, and even more so was his analysis of the nature of one-party regimes and their consequences for democratic politics. Similar constraints on effective partisan representation and integration were explored for the non-Southern states as well some years later. (2) A systematic engagement with the often apolitical, ahistorical (or acontextual) models developed by early national election studies (survey research), and a challenge to their dominant conclusions that voters were largely incapable of fulfilling the roles specified by democratic theory. (3) The first systematic study of critical elections/realignments as major vectors of transformation in the electoral and political system.

Biographical Summary

Valdimir Orlando Key, Jr. was born in Austin, Texas on 13 March 1908. He spent his childhood in the very small West Texas town of Lamesa, later obtaining a BA from the University of Texas at Austin in 1929, and an MA degree at the same institution in 1930. V. O. Key, Jr. then moved to the University of Chicago – then perhaps the premier institution for studying American politics in the United States – and received his doctorate there in 1934. His early professional years were devoted to teaching and, later, to work in Washington for the Social Science Research Council and, subsequently, as part of the technical staff of the National Resources Planning Board during the heyday of the New Deal. Further Washington experience came his way during World War II with a three-year stint at the US Bureau of the Budget (now the Office of Management and Budget). His academic career took him first to Johns Hopkins University and thence to Yale and Harvard Universities, the latter from 1951 until his untimely death in Cambridge, Massachusetts, on 4 October 1963. The long-standing illness to which he eventually succumbed did not prevent him from moving to the very front rank of American political scientists of his generation. The reasons for this fame – a reputational survey of 1965 by A. Somit and J. Tanenhaus placed him then in a clear first position – will be concisely discussed below.

Scientific Contribution

As a Southerner, and at a time when the South was far more a region apart from the rest of the American polity than it is now, Key proved the ideal scholar to provide a comprehensive description and analysis of the South's *apartheid* political order, and its massive influence on national politics, very shortly before its demise. This study, *Southern Politics in State and Nation* (1949), provided a detailed portrait of politics in each on the eleven former Confederate States at the time of writing, as well as analyses of the region's influence on congressional politics; and – an important contribution in its own right – an extended summary statement on the nature and consequences of one-party systems for the representation of public opinion through elections. The craftsmanship is meticulous and innovative, with a mixture of 'thick description' of persons and forces at work based on extensive interviewing, along with the skilful deployment of charts and maps based upon aggregate returns from referenda and primary and general-election returns. More than half a century later, *Southern Politics* still repays the reader's attention.

Quite a lot of Key's basic approaches to the study of American politics, and his personal value commitments, can be found in these pages. First, and obviously, lies the exceptional historic and contemporary importance of 'sectionalism' (major regional differences based on economy, political subculture and experience) in the study of American politics. This point is worth stressing, since with the advent of national scientific surveys of American voters and their behavior in and after the 1960s, this dimension strikingly faded from view in Americanist political science for a protracted period. Secondly, *Southern Politics* underscored the importance of history and historical experience in shaping the confines of today's electoral politics. It is thus perfectly appropriate to view Tennessee politics in the 1940s (and later) in light of the polar oppositions that were displayed in a June 1861 referendum on the state's secession from the Union. This concern to cite present reality in its developmental context was also, however, to run counter to mainstream preoccupations within political science, as the quest for 'scientific regularities' variously led to embracing concepts and models derived from social psychology or economics coming to the fore.

Finally, Key's democratic value commitments, which informed his entire published output across his professional lifetime, are presented in clear view in this magisterial work. Several points about how these views were expressed deserve mention here. Key made no pretension to 'grand theory,' and imported no elaborate conceptual schemes from great Europeans such as Marx or Weber (see Marx, Karl (1818–83);

Weber, Max (1864–1920)). Like many in his and a somewhat earlier generation of American political scientists, his intellectual focus was American to the core, and concentrated on the gap between the democratic promise embedded in the national political culture on one hand, and real-world antidemocratic practices and realities on the other. These latter obviously abounded in the Southern politics he studied, and this gap represented the chief analytic problematic of his lifetime. As he demonstrated in great detail, in the kind of disorganized and exclusionist politics of his South the have-mores profited and the have-lesses lost out as a matter of empirical fact.

At the same time, Key's was a mind which was strikingly subtle and nuanced. Not for him were the sledgehammer blows of Beard (1913), or other notable writers in the American Progressive tradition. Rather, he very carefully spelled out the structure of a given state of political affairs, equally carefully pointed out the vastness of the gap between ideals and empirical reality, and invited his readers to reflect on this gap and how it might be overcome. He was an optimist about the extent this could be accomplished in time – as scholars shaped by the political crises of the 1960s and 1970s often were not. Thus, his hopes for his native region rested to a significant degree on the longer-term effects of industrialization and urbanization on its society and politics. In retrospect, these hopes were to be realized, though only in the context – he was no prophet, after all – of a massive federal intervention in the 1960s, the 'Second Reconstruction,' fuelled by the civil-rights revolution; and, not least, by the USA's foreign-policy requirements in a postcolonial world.

His later major studies displayed his awareness that there were other impediments to the realization of his ideal, the expansion of the electorate's effective role in politics through the instrument of party competition and political choice. In *American State Politics* (1956), Key devoted his attention to several of these impediments: the impact of direct primaries and other regulations of party activities on party organization, including the multiplication of uncontested seats in legislative bodies; what he calls the 'lottery of the long ballot,' i.e., the separate election of a wide range of state office-holders; and the shifting of major state elections away from coincidence with presidential elections and 'national tides' to off years, where, incidentally, voter turnout is nearly always substantially smaller than in presidential years. Key was clearly concerned about the implications of such developments for the integrity of parties as vehicles for individual and collective choice at elections. As **Table 1** below shows on just one of these dimensions, his forebodings have been more than amply realized in the long generation since his death.

Table 1 Insulation effects: states having at least some gubernatorial elections coinciding with presidential elections, 1936–2000

Year	*No. of states*	*Total no. of US reps. in these states*	*Total US reps. in these states (%)*
1936	35	313	72.0
1956*	29	225	51.7
1984	13	58	13.3
2000	11	52	12.0

*Year of publication of *American State Politics*

In his last years, V. O. Key increasingly devoted his attention to the challenges he saw in the development of survey research, both academic and applied. This was to issue in two works, *Public Opinion and American Democracy* (1961) and – posthumously – *The Responsible Electorate* (1966), and a number of articles where criticism was perhaps more pointed. He was vigorously opposed to political-science approaches that appeared to eliminate politics from their analytic schemes. He was alarmed by the potential for manipulating the public that was already (if by today's standards dimly) visible in applied 'market research' by candidates and their media and polling staffs. For, in his view, public opinion ultimately was an 'echo chamber'; and the quality of its output was heavily dependent upon the input provided by political elites and their consultants. Finally, he was convinced that the survey-research portrait of voters as in the main know-nothings (or know-very-littles) drastically underestimated voters' practical political intelligence and capacity for purposive, rational pursuit of political choice in accordance with their interests. On one major point raised in *The Responsible Electorate* – the distinction between interelection 'switchers' and self-Identified partisan independents – his view was later to receive substantial confirmation in a 1981 study of panel surveys by Morris Fiorina (1981). In any event, Key's last work made its own real contribution to the subsequent explosion of 'issue-voting' studies and, eventually, to a much more sophisticated and politically-centered survey-research enterprise.

Assessment of Key's Professional Impact and Current Importance

As the consummate professional that he was, V. O. Key devoted himself to the well-being and improvement of the political-science profession in countless ways. One example, at a time when statistical knowledge within the profession was still pretty much at a primitive level, was his little 1954 volume, *A Primer of Statistics for Political Scientists*. Another was his textbook, *Politics, Parties and Pressure Groups* (Crowell, NY, 1942–1964), which was far the best in its field and extended his teaching to generations of students. He sought to expand the frontiers of knowledge, not only through these and other works, but through myriad contacts with his peers and service to such organizations as the Social Science Research Council and the American Political Science Association.

It may be said that, for two decades or so after his death, Key remained more revered than followed by the political-science mainstream. His was always a sterling example of outstanding craftsmanship in specifying and executing important research projects that provided new insights into the American electoral process; of an enormous mastery of the data of American politics past and present; and a most exceptional capacity to break new ground by using it in novel ways. At the same time, regionalism and history largely fell out of mainstream concerns; his older South rapidly became, or seemed to become, a museum piece; and for a long time, analysis of

aggregate election data seemed to be under W. S. Robinson's 1950 ban on the uses of ecological correlation. Since then, as problematics and professional interests have shifted somewhat, regionalism and historical depth in the explanation of current states of affairs have seen a notable comeback, and a whole field, American Political Development, has emerged into view. At the same time, ecological regression has emerged as a valuable estimation technique for analyzing voter transitions, e.g., during the critical realignment of the 1850s.

In a real sense, Key's work is more significant today than it seemed to be for some years after his death. Nowhere is this more true than in one major area of research by political scientists and historians alike: the study of critical realignment as a major change process across the span of American electoral, and more broadly political, history. As of 1991 (the last formal count), more than 500 books and articles had been devoted to this subject. While some historians had recognized qualitatively the exceptional turning-point significance of such elections as 1800, 1828, 1860, 1896, and 1932. Key was the first to provide an examination of this as an empirically specifiable problem in his truly seminal 1955 article, 'A theory of critical elections' (1955). It is noteworthy that Key never saw fit to explore the subject further, and one can doubt that he would find the elaboration of models in this field always to his taste. But his was the pathbreaking innovation that truly founded a vast research enterprise that is still underway, and has also attracted the attention of non-American researchers as well (Martin, 2000).

Abstract

John Maynard Keynes (1883–1946), British economist and civil servant. The most influential economist of the twentieth century, he made important contributions to philosophy, political thought, and arts policy. He invented, almost single-handedly, a new branch of economics, macroeconomics, or the theory of what determines output as a whole, as contrasted with microeconomics which studies the forces determining the composition of a given output. He did so in order to destroy the implicit assumption of 'classical' economics that a competitive market economy would always ensure full employment and thus to justify government intervention to maintain full employment. The task seemed the more urgent in the wake of the Great Depression of 1929–1933. The result was The General Theory of Employment, Interest and Money, whose publication in 1936 is conventionally taken to be the start of the Keynesian Revolution. Its main policy fruit was the commitment, till the mid-1970s, by most Western governments, to maintain high and stable levels of employment in their countries. The lack of secure microfoundations for Keynesian macrotheory, as well as the somewhat contentious implications of that theory for the role of governments, has continued to make Keynesian economics controversial; while economic historians have disputed the contribution of Keynesian policy to the 'golden age' of global prosperity running from the 1950s to the early 1970s.

John Maynard Keynes was the most influential economist of the twentieth century. He invented, almost single-handedly, a new branch of economics, macroeconomics, or the theory of what determines output as a whole, as contrasted with microeconomics which studies the forces determining the composition of a *given* output. He did so in order to destroy the implicit assumption of 'classical' economics that a competitive market economy would always ensure full employment; and thus to justify government intervention to maintain full employment. The task seemed the more urgent in the wake of the Great Depression of 1929–33. The result was *The General Theory of Employment, Interest and Money* (hereafter GT), whose publication in 1936 is conventionally taken to be the start of the Keynesian Revolution. Its main policy fruit was the commitment, till the mid-1970s, by most Western governments, to maintain high and stable levels of employment in their countries. The lack of secure microfoundations for Keynesian macrotheory, as well as the somewhat contentious implications of that theory for the role of governments, has continued to make Keynesian economics controversial; while economic historians have disputed the contribution of Keynesian policy to the 'golden age' of global prosperity running from the 1950s to the early 1970s.

His Life

John Maynard Keynes was born at 6 Harvey Road, Cambridge, England on 5 June 1883 into an academic family. He was the eldest son of John Neville Keynes, a logician and economist, and Florence Ada Brown, the daughter of a Congregational divine. He had an outstandingly successful school career at Eton College which was followed by an equally glittering undergraduate one at King's College, Cambridge, where he gained a first-class honours degree in Mathematics, wrote papers on the medieval theologian Peter Abelard and the Conservative political philosopher Edmund Burke, and became President of the Cambridge Union and the University Liberal Club. Of crucial importance to his intellectual and moral formation was his election, in 1902, to the Cambridge Apostles, an exclusive 'conversation' society, where he fell under the influence of the philosopher G. E. Moore, and which brought him the friendship of Lytton Strachey. Moore's *Principia Ethica* remained his 'religion under the surface' for the rest of his life. It taught that the highest forms of civilized life were friendship, aesthetic enjoyments, and the pursuit of truth.

In 1906 Keynes was placed second in the Civil Service Examination, his worst marks being in economics, which he had studied briefly under Alfred Marshall (see Marshall, Alfred (1842–1924)). After 2 years in the India Office, in which he wrote a thesis on probability in his spare time, he started lecturing on monetary economics at Cambridge; in 1909, his thesis won him a fellowship at King's College, which remained his academic home for the rest of his life. His membership of the Bloomsbury Group, a commune of Cambridge-connected writers and painters who lived in the Bloomsbury district of London, dates from the start of his friendship with the painter Duncan Grant, Lyttton Strachey's cousin, in 1908. In 1913 he published his first book, *Indian Currency and Finance,* and served on the Royal Commission on Indian Finance and Currency.

Keynes helped to avert the collapse of the gold standard in the banking crisis of August 1914 which accompanied the outbreak of the first world war. From January 1915 to June 1919 he was a temporary civil servant at the Treasury, showing a notable ability to apply economic theory to the practical problems of war finance. He was against military conscription, and would have been a conscientious objector had his Treasury work not exempted him from military service. When Lloyd George succeeded Asquith as Prime Minister, Keynes (in January 1917) became head of the Treasury's new 'A' Division, set up to manage external finance. He helped to build up the system of Allied purchases in external markets,

while chafing at Britain's growing dependence on American loans and the failure to arrange a compromise peace. Keynes was chief Treasury representative at the Paris Peace Conference in 1919, where he tried unavailingly to limit Germany's bill for reparations, and to promote an American loan for the reconstruction of Europe. His resignation from the Treasury on 5 June 1919 was followed by the publication, in December, of *The Economic Consequences of the Peace*, the book which first brought him international fame. A bitter polemic, informed by both moral passion and economic argument, against the Allied policy of trying to extort from Germany an indemnity which it could not pay, it reflected his revulsion against Lloyd George's leadership in both war and peace, and his fears for the future of European civilization. Unless the Versailles Treaty were drastically revised, 'vengeance, I dare predict, will not limp' (Keynes, 1919, p. 170)

Between the wars, Keynes's life was divided between Cambridge, London, and East Sussex. He was a spectacularly successful investment Bursar of King's College, and despite some major reverses, made about $400 000 for himself over his lifetime – worth $12m. today – out of which he financed a fine collection of pictures and rare books and the building of the Cambridge Arts Theatre in 1935. In London, where he rented a house at 46 Gordon Square, he was, at various times, on the Boards of five investment and insurance companies, the chief one being the National Mutual Life Assurance Company, which he chaired from 1921 to 1937. Between 1923 and 1931 he was chief proprietor and chairman of the Board of the weekly journal, the *Nation and Athenaeum*, contributing regular articles on financial and economic topics. (He remained chairman of the Board of the *New Statesman and Athenaeum* when the two journals merged in 1931.) Between 1911 and 1945, he edited the *Economic Journal*. In the 1920s his ideas on economic policy permeated Whitehall through monthly meetings of the Tuesday Club, a dining club started by his friend and stockbroker, Oswald Falk. In the 1930s, he sought to influence policy through his membership of the Prime Minister's Economic Advisory Council. In 1925, he took the lease of Tilton, a farmhouse in East Sussex, next door to Charleston, where Duncan Grant lived with the painter Vanessa Bell. This move coincided with his marriage to the Russian ballerina, Lydia Lopokova, who gave his life the emotional stability it had previously lacked, and which provided the necessary background for sustained intellectual effort.

In the 1920s, the postwar European inflations, succeeded in Britain by heavy unemployment, formed the background to his two theoretical books *A Tract on Monetary Reform* (1923) and *A Treatise on Money* (1930) which dealt with the causes and consequences of monetary instability, and their remedies. These theoretical exercises were punctuated by two notable polemical pamphlets *'The Economic Consequences of Mr. Churchill'* (1925) and *'Can Lloyd George Do It?'* (1929), written with Hubert Henderson. The first attacked Churchill's decision, as Chancellor of the Exchequer, to put the pound back on the gold standard at an overvalued exchange rate against the dollar; the second was a plea for a large public-works program. Reconciled to Lloyd George in 1926, Keynes attempted to provide the Liberal Party with a social philosophy of the 'middle way' between individualism and state socialism, suitable for an inflexible industrial structure. Regulation of demand, he would later write, was the only way to maintain capitalism in conditions of freedom (Keynes, 1936, p. 381, 1940, p. 123).

The Great Depression of 1929–32, together with technical flaws in *A Treatise on Money*, took Keynes back to the theoretical drawing board. What now seemed to be needed was not an explanation of Britain's 'special problem' of persisting unemployment, but an explanation of how aggregate output could collapse, labor remain unused, and global depression persist in a world in which resources remained scarce. From the autumn of 1931 to the summer of 1935, Keynes worked on a new book of theory, initially entitled *'The Monetary Theory of Production*.' He was helped not just by older economists like Ralph Hawtrey and Dennis Robertson, but by Roy Harrod and a 'Cambridge Circus' of young disciples led by Richard Kahn. There was just one major pamphlet in these years, *'The Means to Prosperity*,' written in June 1933. On a trip to the United States in 1934 to study the New Deal first-hand, he wrote: 'Here, not in Moscow, is the economic laboratory of the world.'

The GT, published in February 1936, tried to demonstrate both that 'underemployment equilibrium' was logically possible, and how monetary manipulation by the central bank combined with an extensive 'socialization' of investment could maintain full employment. The first proposition, in particular, divided the economics profession, since it rejected the 'classical' thesis of a self-equilibrating economy. The publication of the GT confirmed the breach between Keynes and Dennis Robertson and Hubert Henderson, his chief collaborators in the 1920s; at the same time it marked the birth of a 'Keynesian school' of economics led by Richard Kahn and Joan Robinson (*see* Robinson, Joan (1903–83)) at Cambridge, Roy Harrod and James Meade at Oxford, and Nicholas Kaldor at the London School of Economics. In the United States, the GT supplied the younger generation of (mainly Harvard-trained) economists with a theoretical rationale for the New Deal. Keynes himself joined in the fierce controversies which his book generated, even though he was severely incapacitated, from May 1937 to March 1939, with heart disease. As another European war, and with it, the return to deficit-financed full employment became increasingly likely, Keynes sought to win acceptance for his Revolution by showing how the managment of aggregate demand to avert depression could just as easily be used to contain inflation in a war economy.

The upshot was his pamphlet *'How to Pay for the War*' (1940), which won the approval of his arch critic Friedrich Hayek (*see* von Hayek, Friedrich A. (1899–1992)), and whose logic influenced Kingsley Wood's war budget of 1941. Restored to a semblance of health by his doctor, Janos Plesch, Keynes himself returned to the Treasury in August 1940 as unpaid adviser to the Chancellor of the Exchequer, and remained its dominating force for the rest of his life. Elevated to the House of Lords as Baron Keynes of Tilton, his influence was felt in the Beveridge Report on Social Security in 1942, and in the Employment White Paper of 1944 which pledged the government to maintain a 'high and stable level of employment' after the war. In 1942, Keynes became chairman of the Council for the Encouragement of Music and the Arts (CEMA), a wartime innovation which, transformed into the Arts Council of Great Britain shortly before he died, inaugurated permanent state patronage of the arts.

The American demand that, in return for Lend-Lease, Britain scrap its imperial preference system after the war, inspired Keynes to his last great constructive effort, his plan for an International Clearing Union (1942). This was designed to shift balance-of-payments adjustment from debtor to creditor countries, so as to avoid the externally generated deflationary shocks which had spread depression under the gold standard. The Bretton Woods Agreement of 1944, which set up a system of fixed, but adjustable exchange-rates and two new institutions, the International Monetary Fund and the International Bank for Reconstruction and Development, fell short of Keynes's hopes. The abrupt US cancellation of Lend–Lease in August 1945 led him to undertake the fifth of his six Treasury missions to the United States to secure an American grant or interest-free loan of $5bn. Forced to accept a semi-commercial loan for an amount far less than he had requested, Keynes gave a brilliant defence of his policy in his last speech to the House of Lords on 7 December 1945.

On 21 April 1946, worn out by his labors, he suffered a fatal heart attack at Tilton, a little short of his 63rd birthday. In an imposing memorial service at Westminster Abbey, Clement Attlee, the prime minster, headed a list of mourners drawn from all walks of life.

Major Contributions

Keynes's main contributions to economics can be grouped under three heads: the theory of deep economic fluctuations; the theory of effective demand; and the technique of stabilization policy based on the second.

The Theory of Economic Fluctuations

This cannot be wholly understood apart from Keynes's distinctive theory of probability. In his *A Treatise on Probability* (1921), his main contention was that probability is not statistical, but is a logical relationship between the premise and conclusion of an argument which fell short of demonstrative proof. Like Frank Knight (who however used a statistical theory of probability), Keynes distinguished between risk, or situations when agents can form probabilities and thus insure against loss, and uncertainty, when 'there is no scientific basis on which to form any calculable probability.' He wrote in 1937: "Thus the fact that our knowledge of the future is fluctuating, vague and uncertain, renders wealth a peculiarly unsuitable subject for the methods of the classical economic theory' (Keynes, 1937, p. 113). This may be contrasted with the modern mainstream view that agents maximize with known probability distributions, so that market-clearing models are the most appropriate for analyzing economic behavior. Keynes himself identified as a tacit axiom of the classical theory of the self-regulating economy that 'at any given time facts and expectations were ... given in a definite and calculable form' (Keynes, 1937, p. 112).

Keynes's theoretical work in the 1920s is devoted to unpackaging the Quantity Theory of Money (QTM) which ruled out, by assumption, the possibility that monetary disturbances can have 'real' effects on the economy. This might be true in the long-run, Keynes remarked acidly, 'but in the long-run we are all dead' (Keynes, 1923, p. 65). Keynes used the quantity of money *equation* to show that changes in the quantity of money can unsettle business expectations and the distribution of income, thereby causing short-run fluctuations in the level of business activity. In doing so, he emphasized the use of money as a 'store of value' or hedge against uncertainty, and the distinction between fixed and flexible prices. Thus in the *Tract on Monetary Reform* he wrote: 'The *fact* of falling prices injures entrepreneurs; consequently the *fear* of falling prices causes them to protect themselves by curtailing their operations' (i.e., adding to their cash balances) (Keynes, 1923, p. 34). In the *Treatise on Money*, he argued that the disturbing effects of money can arise not just from inflationary or deflationary policies, but from *autonomous* changes in business sentiment. Much of the *Treatise* is devoted to analyzing the consequences of short-run changes in the 'propensity to hoard' or 'velocity of circulation,' which Keynes identifies, by means of his 'Fundamental Equations,' with the emergence of windfall profits and losses, and a disequilibrium between saving and investment. Keynes shows how disequilibrium prices produce an oscillation of boom and slump round a (notional) full-employment equilibrium. But such equilibrium is achieved accidentally, in the absence of appropriate monetary policy.

The chief theoretical point which emerges from these two works is the instability in what Keynes would later call the liquidity-preference schedule. His claim was that, in a variety of situations readily encountered in economic life, hoarding money or savings can yield superior utility to investing them, and that this, combined with 'sticky' wage and price contracts, can explain quite prolonged lapses from full employment. His contribution up to 1930 was largely a summation of the monetary theories of Irving Fisher (see *Fisher, Irving* (*1867–1947*)) and Knut Wicksell, and is properly regarded as a contribution to the theory of economic fluctuations, with increased emphasis on volatile expectations. Like Fisher, Keynes advocated a monetary policy of keeping domestic prices stable; this might be incompatible with adherence to the international gold standard, an institution which Keynes dismissed as a 'barbarous relic' (Keynes, 1923, p. 138).

The Theory of Effective Demand

Keynes's revolutionary contribution to economics lies not in his theory of business fluctuations but in his theory of how aggregate output is determined. This is the subject matter of his GT. The QTM was a theory of the price level, when the levels of output and employment were explained in real, nonmonetary terms. Following a suggestion from Ralph Hawtrey, Keynes agreed in 1930 that "it will probably be difficult in the future to prevent monetary theory and the theory of short-period supply from running together" (Keynes, 1930, p. 146). This was the start of macroeconomics.

The core of the GT is the theory of effective demand. It tells how, when something happens to reduce aggregate demand, aggregate supply and aggregate demand are reconciled, not through falls in the price-level of output, but by a reduction in its quantity. It is a short-period theory: prices adjust only after, and as a result of, the fall in output and employment, and even then not completely. In the short-run, the volume of output in

an economy is determined by the money demand for that output. The GT is the theory of what determines the level of money demand for output.

In Keynes's notation $Y = C + I$. This tautology simply means that National Income (Y?) is equal to the sum of the expenditure on National Output, divided into consumption spending (C) and investment spending (I). Consumption expenditure is governed by Keynes's 'consumption function,' based on the 'psychological law' that consumption (and therefore saving, which is $Y - C$) is a stable fraction of total income, and that the marginal propensity to consume is less than unity. In a progressive economy the gap beween consumpion and production must be filled by investment if full employment is to be maintained. The amount of investment is determined by the relationship between what the investment is expected to yield over its lifetime ('the marginal efficiency of capital') and the cost of borrowing the money needed to finance it (the rate of interest). Both are subject to uncertain expectations. Consumption is the stable element in demand; investment the volatile element. Thus, what the community wishes to save may at a particular moment exceed what businessmen want to invest. The revolutionary claim of the GT is that when this happens, the divergent plans are brought into equality by a reduction in the level of income (output). Moreover, if the consumption function is known, it is possible to show, by a mathematical formula (Kahn's multiplier), by how much the community's income or alternatively employment must change to reconcile divergent saving and investment plans. The novelty of Keynes's treatment, as compared not just with the older theory, but his own *Treatise on Money*, was to demonstrate that an economy might be in equilibrium, with saving equal to investment, and aggregate demand equal to aggregate supply, at less than full employment.

Critics fastened on the most contentious feature of the new doctrine, the theory of 'under-employment equilibrium.' They denied that this was a genuine equilibrium; it was a disequilibrium state, frozen by the assumption that certain prices were fixed. Flexible interest rates and wage rates would always ensure the desired level of employment, whatever was happening to aggregate demand.

Keynes could have defended his position by saying that his fixed-price assumptions were realistic but he set out to expose the logical flaws underlying the implicit classical price-adjustment story. He denied, first of all, that the interest rate was, or could be, determined in the market for saving and investment, since the quantity of saving depends on the level of current income. This was the basis of his view that it is changes in income that equilibrate saving and investment plans. In place of the classical theory of interest, he offered his liquidity-preference theory of interest, which makes interest the price for giving up cash. The greater the liquidity-preference of wealth-holders, the higher the yield they will demand for switching from cash into bonds or other securities. Insofar as the rate of interest *does* move in response to a fall in investment demand, it will be in the wrong direction, since the "same circumstances which lead to pessmistic views about future yields (of capital assets) are apt to increase the propensity to hoard" (Keynes, 1937, p. 118).

As far as wage flexibility is concerned, Keynes agreed with the orthodox view that the *real* wage is inversely related to the quantity of employment, but denied that real wages are determined in the labor market by money-wage bargains, since an all-round reduction in money-wages might, by reducing the general price level, leave the real wage unaffected. The effect of a 'flexible wages policy' thus depended entirely on its impact on the components of aggregate demand-consumption and investment – which might well be unfavorable.

Keynes conceded that, in time, the decline in employment (or money-wage rates) would, by decreasing the amount of money required to satisfy the business demand, lower the rate of interest required to satisfy the "propensity to hoard" (Keynes, 1937, p. 118); he also thought that, after a slump, a shortage of capital goods would develop which would revive profit expectations" (Keynes, 1936, pp. 317–318). In short, a slump might eventually bring about the price adjustments which according to the classical economists were supposed to prevent the slump from occurring. He doubted, though, whether even longer-run forces would ensure a gravitational pull toward full employment. 'We oscillate,' he wrote, "round an intermediate position, appreciably below full employment and appreciably above the minimum employment a decline below which would endanger life" (Keynes, 1936, p. 254).

Despite nonacceptance by the leading economists of key elements in Keynes's macroeconomic model (Dennis Robertson, in particular, made a damaging attack on his theory of interest), critics were driven to argue for their positions within the analytical framework Keynes had set up. Macroeconomic analysis became part of the economists' tool kit, even if Keynes's own conclusions were rejected.

Stabilization Technique

Keynes's three main theoretical books were all aimed at providing justifications for conscious attempts to stabilize output and employment at a high level. The quest for output stabilization led directly to the development of National Income and Expenditure Accounts, to enable governments to estimate the size of the 'output' gap – the gap between what the economy was producing and what it could produce at full employment (or, in later refinement, what it could produce when it was growing to trend) – which needed to be plugged by extra spending. Keynes also insisted that the aggregate demand and supply framework of the GT could be used to work out how much spending needed to be withdrawn from an economy to prevent inflation if aggregate demand exceeded aggregate supply.

In principle, stabilization policy can be either monetary or fiscal, or some combination of both. In practice, Keynes rejected the monetary route to managing demand. He did not deny that investment was interest-elastic. But he thought that interest-rate changes, produced by varying the quantity of bank credit, were too slow-moving in their effects on investment; and he was worried that if interest rates were raised to check a boom it would be difficult to bring them down to check a slump, since the expectation of falling rates would increase the 'propensity to hoard.' So he advocated a policy of permanently cheap money, to be buttressed by capital controls and 'under-funding' of the National Debt. This left fiscal policy as the main instrument for preventing both slumps

and inflationary booms. Keynes's fiscal philosophy must be distinguished from Keynesian fiscal policy as understood (and sometimes practiced) after his death. It was based on a sharp distinction between the government's 'ordinary' or current-account budget and what he called the 'capital' budget, made up not just of government spending on capital projects but the economy's total investment. The government's ordinary budget should be balanced at all times, with a surplus earmarked for debt repayment in 'normal' times. It was the task of the capital budget to balance the 'national accounts.' Keynes believed that a great deal of investment was already 'socialized,' that is, subject to public policy even if it was technically private. As he put it in 1943: "If two-thirds or three quarters of total investment is carried out or can be influenced by public or semi-public bodies, a long-term programme of a stable character should be capable of reducing the range of fluctuation to much narrower limits than formerly ... If this is successful it should not be too difficult to offset small fluctuations by expediting or retarding some items in this long-term programme" (Keynes, 1943, p. 322).

Finally, Keynes attached only minor importance to exchange-rate adjustments. His Clearing Union Plan (1942) provided for fixed, but adjustable rates, and this was a feature of the Bretton Woods Agreement (1944). Keynes's attitude – like that of most economists of his day – was governed by price-elasticity pessimism. He preferred countries to use, if necessary, capital controls to protect their balance of payments in the framework of a monetary regime of fixed exchange rates, low tariffs, and automatic creditor lending through international institutions.

Keynes was not an ivory-tower theorist. His theorizing was controlled by real world events. His own investment experience enabled him to identify the 'speculative' motive for holding money; his sense of political fragility led him to concentrate on the economics of stabilization; his civil service experience enabled him to turn theories into workable plans. His economic theorizing was less directly, but still importantly, controlled by his philosophical beliefs, particularly by his conception of the good life and of the conditions of just exchange.

The Legacy

Economics was transformed by its encounter with Keynes. Macroeconomics became for many years a dominant part of the subject; macroeconomic forecasting the main tool of government policy. However, Keynes's doctrines never won universal acceptance, and key aspects of his theoretical and policy legacy have been challenged. The debated issues can be grouped under four heads.

Acceptance of Keynes's Theory

What Keynes bequeathed was not the same as what was accepted. The first theoretical breach came with demonstrations by Pigou (1942) and by Modigliani (1944) that the Keynesian slogan 'quantities adjust, not prices' was true only if money wages were rigid. This became the basis of the 'neoclassical synthesis,' which grafted Keynesian macroeconomics on to classical theory, but left the rigidities unexplained. Milton Friedman's counter-attack was both methodological and theoretical. On the one hand, he argued that it was not acceptable to posit ad hoc supply and demand functions. Second, his own application of neoclassical standards of method to Keynes's aggregate equations – seen in his permanent income hypothesis (1957), the stable demand for money function (1956, 1963), and the theory of the 'natural rate' of unemployment (1968) – undermined the case for Keynesian stabilization policy. Economies were more cylically stable than Keynes had supposed; multipliers were small, or nonexistent; government manipulation of aggregate demand had no permanent 'real' effects, but only raised the inflation rate. These 'policy ineffectiveness' propositions were to be hardened still further by the 'rational expectations' school of Robert Lucas and Thomas Sargent. The tendency of Friedman's critique (popularly called 'monetarism') was to reinsert an updated version of the Quantity Theory of Money into the heart of macroeconomics. It revived the pre-Keynesian notion (adumbrated by Keynes himself in the *Tract on Monetary Reform*) that the most important macroeconomic function of governments was to keep stable the purchasing power of money.

Acceptance of Keynesian Policy

Contrary to widespread mythology, this was patchy. Both the British government and the US Administration committed themselves to targetting 'high' levels of employment, but it is often asserted that US policy only became Keynesian in the early, and German policy in the late, 1960s, and that both Keynesian episodes were fairly brief. Much of this discussion begs the question of what one means by 'Keynesian' policy. Running a budget deficit is no more a sign of Keynesian virtue than is running a budget surplus in boom conditions anti-Keynesian. An alternative argument is that Keynes's influence was exerted not so much through national policies as through the US willingness to provide the rest of the world with reserves and liquidity. However, this likewise begs the question of how 'Keynesian' this willingness was.

The Impact of Policy on Events

For a long time, the canonical view was that Keynesian demand-management policies and Keynesian-inspired institutions (the Bretton Woods system) were mainly responsible for the uniquely successful employment and growth performance of most countries in the 1950s and 1960s. Today most of the credit for the 'golden age' is given to opportunities for 'catching up' with American technology, recession-proof military spending by the US, and high levels of 'social' spending.

In the 1950s and 1960s it was common to argue that Keynesian policy helped to save capitalism by removing the scourge of mass unemployment. (In Marxist terms, it legitimized the capitalist order.) By the 1970s it was being argued that it endangered the long-run survival of capitalism by producing rising inflation, an expanding public sector, and increasingly draconian wage and price controls.

The Current Debate Over Keynesian Economics

According to the monetarist-cum-rational expectations schools, Keynesian economics failed the predictive test: it led to

inflation, still worse 'stagflation.' In the 1970s, Keynesian policies were attacked for ignoring the existence of a 'natural' rate of unemployment, and (by the Virginia or Public Choice school) for assuming that politicians wanted to maximize the collective social welfare, rather than their own individual utilities. Taken together, these two attacks offered a forceful argument against the use of discretionary fiscal and monetary policy to balance economies.

The use of models of economies with nominal rigidities is still general, but whether these rigidities are to be taken as given is much more questioned than in 1950s and 1960s. The dominant 'supply side revolution' of the 1980s chiefly was concerned to dissolve rigidities seen as institutional by deregulating labor markets. Against this, the 'new Keynesians' explained how sticky prices are rational because of transactions and information costs, and how shocks to demand can destroy both physical and human capital. These explanations seemed both to strengthen and weaken the case for Keynesian macroeconomic policy. On the one hand, they gave renewed intellectual respectability to stabilization policy. On the other hand, by explicitly introducing inflation into their analyses, they conceded the existence of a rate of unemployment (theso-called NAIRU or Non-Inflation Accelerating Rate of Unemployment) below which unemployment could not be pushed by manipulating demand. Finally, against the mainstream profession's use of Bayesian statistics and decision theory to model agents' behavior, a minority school of 'Post-Keynesians' continues to assert the fundamental nature of Keynes's attack on the rationality axiom.

An interim judgment on the Keynesian Revolution would be that the main body of classical economics was too well-entrenched to be overthrown by the frontal assault he mounted. The notion that uncertainty was at the heart, rather than at the financial margins, of economic processes, proved too subversive of the science economics claims to be, to be acceptable. Most economists would say today of Keynes what Marshall said of Jevons: "His success was aided even by his faults ... he led many to think he was correcting great errors; whereas he was really only adding important explanations." Whether this will be the final verdict is still questionable.

Abstract

Keynesianism assigns to the State the responsibility to regularly intervene in the operation of the economy so as to maintain its performance at a high level. It stresses the fine-tuning of short-term fluctuations by discretionary policies. It was not born with Keynes (who probably would be hostile to it), but with macroeconomics, national accounting and statistics in the post-war period. Stagflation of the 1970s was its downfall. Today paradoxically the attacks from the 'rational anticipations' school converge with new readings of Keynes. A government of the economy, limited in scope and in ambition, is permissible via a rule-based macroeconomics.

This reprint from the 1st ed offers the view on Keynes and the so-called Keynesianism as it was held before the recession of 2008 and the following years. Therefore the chapter is a historical document and at the same time proof that the knowledge production in economics and other social sciences is not always in accord with developments just around the corner. Even former opponents of Keynes started to think differently about his role and the appropriateness of an economic policy which follows some of his advices.

Keynesianism, whatever its variants, assigns to the State the responsibility to regularly intervene in the operation of the economy so as to maintain its performance at a high level of employment and growth (Hall, 1989). Keynesianism believes in the effectiveness of this intervention. From Keynes' analysis of the preference for liquidity and the economic crisis of the 1930s it has retained a definite skepticism concerning the effectiveness of monetary policy. Investment and consumption are held to be little affected by interest rates; it therefore suffices to have a monetary policy that maintains interest rates at a sufficiently low level. On the other hand, Keynesianism stresses counter-cyclical management of overall demand by means of fiscal and budget policies: financing expenditures by public borrowing in case of recession; seeking a budget surplus to hold down inflation in the rising phase of the cycle. Fiscal constraint can be relaxed to finance welfare programs. This is a decisive change with respect to classical economics that deemed a balanced budget to be the highest priority. The Keynesian stimulus works via a sort of self-fulfilling prophecy concerning investment and demand. Prewar policy held to the contrary that the modest means available to the government was a guarantee for democracy, allowing it to stand up to populist excesses and to unlimited demands from special-interest groups.

Keynes would have been hostile to Keynesianism. In all likelihood he would have espoused, although in different terms, the criticism expressed by Friedman (1968) and Lucas (1976) towards the Keynesians' conception of State intervention in the economy. But this criticism, albeit radical (and essentially well taken), is aimed less at the principle than at the modalities of an effective State intervention. Keynesianism, for all its '*naïveté*,' has managed to make this intervention accepted. This is the paradox that ensures a long life for intellectual and political debate about Keynes' writings. This contribution is divided into three sections: a history of the reception encountered by Keynesian ideas: criticism of these ideas, and the relevance of Keynes today.

The Reception of Keynesian Ideas

Keynesianism was not born with Keynes. Hicks (1937) notably formalized the IS-LM curves that jointly determine the global income and the rate of interest, via the relations between investment, savings, demand and supply of money. Samuelson (1948) provided the analytical frameworks of macroeconomic policy. Put briefly, the synthesis thus established, neoclassical in spirit, resituates Keynes' work in the conventional framework of market equilibrium. It eliminates the role of agents' expectations, which was decisive for Keynes (as well as eliminating the role of the 'state of confidence'), and replaces it with a mechanistic vision of the economy that is reduced to a few global parameters. Phillips (1958) then added the curve linking wage increases, rising prices and the unemployment rate. The development of national accounting and statistical apparatus provided the basis for econometric modeling. Little by little economists, following in this respect the theory of economic policy elaborated by Tinbergen (and drawing politicians and political discourse in their wake), came to espouse the use of macroeconomic models for the quantitative evaluation of State policy. Keynesian policy is fundamentally a policy designed to fine-tune short-term fluctuations in the economy. If short-term forecasts given by a model are accurate, then the long-term evaluation of the effects of a policy is presumed to be reliable. The long-term outcome is engendered by a carefully constructed chain of short-term periods. Keynes thought, on the contrary, that the agents' view of the long term had a direct effect on their current behavior.

From the 1930s to the 1950s the reception of Keynesian ideas spread through three channels: the influence of professional economists' expertise on political decision making (seeking new explanations for the economic crisis); new demands formulated by political parties (themselves conditioned by previous experience); and the capacity of Keynesian ideas to spawn broad political coalitions. The configuration of history fostered the convergence of these three channels: the heritage of the war economy (when the 'young' Keynesians had

demonstrated the effectiveness of State organization and intervention); the needs of reconstruction (which called for a high level of public investment), and the expansion of social policies aimed at achieving full employment. In the light of the prewar risk of confrontation between the labor agenda (leading to nationalization of the means of production) and that of capitalism (*laissez-faire* liberalism), Keynesianism offered a compromise. Full employment and sustained growth could be achieved in a capitalist economy through the judicious use of macroeconomic management (without interfering with the management prerogatives of private capital). Labor could see full employment guaranteed, and capital could continue to control investment.

But in order for Keynesian policy to be effective two structural conditions were necessary: a system of appropriate institutions; and a common language and beliefs shared among the actors in the economy. These conditions were fulfilled to various degrees depending on the country – more highly developed in Great Britain and France though differently, than in the United States or Germany. The State must be linked to the actors by a set of institutions that structure the flow of information and resources. These institutions ensure a common assessment of the economic situation and provide security for anticipations (notably via property rights and contract law). A relationship of confidence between the central bank, the State, and financial markets is crucial for the financing of public debt and establishing regulation of the banking system. At the same time, shared views of the expected and legitimate role of the State must spread throughout the economy and society. This 'conventional' foundation creates the state of confidence enabling each actor to constitute favorable anticipations (of demand and investment). The combination of these anticipations is self-fulfilling of the forecast projected by the macroeconomic model; it allows State intervention to attain its goals. This double system of institutions and shared conventions paradoxically ensures the effectiveness of Keynesian policy. Without this system, Keynesian policy is nothing. This is what the Keynesians forgot. They consequently come to believe in the State as a *deus ex machina*. In neglecting the question of expectations they left the way open for the school of rational anticipations. The return in force of market economics and neo-classical rationality was the outcome.

Criticism of Keynesianism

A series of attacks, some old (Hayek, Buchanan) and others recent or renewed (Friedman, Lucas, Sargent), converged in the late 1960s and early 1970s, leading to a collapse of Keynesianism.

Hayek and Buchanan had paved the way, one by rejecting any sort of validity for macroeconomics in itself, the other by demolishing the myth of the State as an enlightened despot. Keynesianism opens the floodgates of inflation by facilitating uncontrolled creation of credit. Then come wage and price control policies that eliminate inflation at the cost of much higher unemployment than that which would have resulted under a stable currency regime (Hayek). Economics can be seen as a science that gives people greater control over their environment, but it has no command over politics. Governments are more interested in collecting the maximum number of votes than in pursuing the public good (Buchanan).

The Phillips relationship had given Keynesian policy its missing link: that of setting wages. Fine tuning efforts could focus on the inflation/unemployment dilemma: how much unemployment is needed to ensure price stability? The stagflation of the 1970s (high unemployment and high inflation occurring simultaneously) was its downfall. Friedman reintroduced anticipations. He showed that the trade-off between inflation and unemployment is only temporary: it stems from inflation that is not anticipated by agents. Eventually unemployment returns to its natural rate, which is determined by structural socioeconomic characteristics, but at the price of higher inflation. Discretionary monetary policy cannot durably stabilize either interest rates or unemployment at low levels. Keynesians situate themselves in a world where everyone anticipates that prices will remain stable, and where this anticipation persists no matter what happens to prices and wages. This world has vanished. Friedman updated his 1948 program: replacing a discretionary monetary policy with public adoption by the monetary authorities of a set rule. In the present instance this means: setting a growth target for the money supply (using a specified monetary aggregate); avoiding sudden changes, not overreacting to events. In 1948 this 'monetarist' framework had received no attention. Economists had adopted the highly flattering position of 'advisor' to the managers of the economy (and thereby justifying the development of their profession). The contrast between the massive unemployment of the Great Depression and the success of the post-war economy had persuaded the economy's managers of the efficacy of systematic State intervention. 'Friedmanian' rules are now widely followed by monetary authorities (like the Federal Reserve Bank or the European Central Bank).

Lucas's criticism was aimed at the use of macroeconometric models. The theory of economic policy (Tinbergen, 1952) underlying this use is invalidated by the fact that actors adapt their rules of decision to modifications in economic policy. The variables controlling economic policy are thus endogenous to the system; the structure of the models varies with economic policy. No reliable projection of future behavior and trends can be obtained by extrapolation of series and correlation with the past. In order for a change in the rules to have a chance of being effective (i.e., leading to foreseeable trends) it must be publicly debated and understood by the actors in the economy. Once again, despite a few pockets of resistance, this criticism ultimately dealt a fatal blow to substantive macroeconomics 'defined by itself to be the body of expertise … devoted to the development and refinement of forecasting and policy evaluation methods' (Lucas, 1980, p. 250). This discipline failed to foresee the return of economic growth at the dawn of the twenty-first century. But this has not prevented the teaching of macroeconomics to continue in academia.

Now that the din of the dogmatic battles has ceased, a more balanced assessment is possible. The structuring role of the anticipations of agents is now recognized. They introduce an irreducible element of unpredictability. What counts in the dynamics of the economy is action and coordination.

Economic policy must abandon the aim of influencing the course of events by substantial and discretionary means. Its field of action relates to the rules that serve as the framework of reference for private forecasts and actions. At bottom, for these rules to be effective they must be debated and made public. They leave room for interpretation in action and for innovation. They provide a framework that can be publicly revised and adjusted in keeping with the results obtained. This does not imply, however, an absence of concern for joblessness and full employment, but rather a clearer consciousness of the properties of various policy instruments and how they complement each other. The unemployment rate can no longer be a direct target of economic policy. Measuring an unemployment rate under full employment is meaningless. Firms and employers have many options other than unemployment at their disposal for adjusting to fluctuation in the demand for products and to the outlook for innovation. Satisfactory allocation of social risks is the task of welfare economics. Providing a framework of stability and security that safeguards the anticipations and terms of agreements concluded – this should be the essence of economic policy (Lucas, 1976). But can this modest objective satisfy the body of professional economists, who are much more numerous than in the past and permanently accustomed to the comforts and remuneration of policy expertise?.

The Relevance of Keynes Today

Keynesianism is dead, but what of the writings of Keynes himself? In his ferocious criticism of Tinbergen in 1939 Keynes already expressed the arguments that were later expanded by Lucas (who did so without making any reference to the writings of Keynes). This criticism originates in Keynes's *Treatise on Probability* (1921). As early as this work he understood that the problem is a double one, that of measurement and that of 'passing from statistical description to inductive generalisation' (Keynes, 1939, p. 566). If all causal factors must be measurable for economic policy to be subjected to statistical tests and forecasting, 'it withdraws from the operation of the method (of Tinbergen) all those economic problems where political, social and psychological factors, including such things as government policy, the progress of invention and the state of expectation, may be significant' (1939, p. 561). Keynes was likewise prudent concerning the arithmetic of the multiplier. Lastly, for Keynes the prime target of monetary policy was the value that actors accord to the conventions that they follow on financial markets. It is the state of confidence that is important, and not directly interest rates and unemployment.

'Neo-Keynesians' have counter-attacked. They integrated into the Keynesian scheme rational anticipations and the possibility of exogenous shocks and of constraints on individual supplies and demands. But in so doing they remain open to these criticisms of Keynes. And by insisting on the rigidity of costs, their recommendation of wage flexibility paradoxically converges with that of liberals attached to the idea of reducing the natural unemployment rate. The 'post-Keynesians' (Davidson, 1991) insist on the radical and non-probabilistic uncertainty that surrounds the decision-making of economic agents. They thus move closer to the institutional (and not solely political) content of Keynes' message. They attempt to express his relevance to the current context. This uncertainty stems from an instability in the overall trajectory of the economy. Institutions must be created to construct a 'corridor' that restricts the range of directions that actions can take. Following Keynes' intuition on inference and probability, it should probably be added that institutions allow people to make judgement and inference on situations of action which are well-founded and secure.

It is time to leave behind the paralysis of opposing schools and dogmatic assumptions (in particular regarding States vs. the market, or the nature of the market, or rationality). Too often a worthwhile idea is rejected, on the pretext that it comes from the opposing school. Little by little a macroeconomics of rules is expanding in which government of the economy by the State is permissible (a posthumous victory for Keynesianism). But, as thought Keynes, this government must be limited in scope and in ambition (Skidelsky, 1999). The dynamics of the economy are above all the result of the actions, anticipation and coordination of the actors. These actors are diverse in terms of their identities, their means and ends (and in the relationship they establish between means and ends). The knowledge they have acquired of their terrain renders their action irreplaceable in a context of uncertainty. A framework of democratically debated, stable and foreseeable rules seems necessary for the implementation of collectively effective actions. But the debate is shifting to the status of these rules (are they prescriptive rules, or guidelines open to interpretation in action?) and to the status of macroeconomic variables (objectives, constraints, or simple by-products of market activity?).

Abstract

Motoo Kimura (1924 –94) was a leading Japanese geneticist and the successor to Fisher, Haldane, and Wright in developing the mathematical theory of evolution. His scientific life can be divided into two parts. In the first part he used his mathematical skills to extend the existing theory, especially where stochastic processes are involved. In the second part, he developed the neutral theory – the idea that the great majority of changes at the nucleotide level are driven by mutation and random drift rather than natural selection. The theory, at first controversial, is now largely accepted for molecular changes and has led, among other things, to the molecular clock.

Motoo Kimura was Japan's foremost population and evolutionary geneticist. He is best known for his neutral theory of molecular evolution, which asserts that the great majority of evolutionary changes at the DNA level are driven by mutation and random survival of mutant genes, rather than by natural selection. He was also a major contributor to the mathematical theory of evolution and population genetics.

Life

Motoo Kimura was born on 13 November 1924, in Okazaki, Japan. Early in his life he was fascinated by plants and had a deep interest in their structure. He also displayed an early talent for mathematics. He was admitted to the National High School in Nagoya in 1942. Here, thanks to a knowledgeable and sympathetic teacher, he studied the chromosomes of lilies. This institution also provided his first contact with biometry, and he realized for the first time that he could use his mathematical skills to study biological problems. In 1944 he was admitted to the Kyoto Imperial University.

Normally Kimura would have enrolled in the Faculty of Agriculture to study with the internationally respected geneticist, Hitoshi Kihara. But agriculture students were being called into military service, while botany students were not. So, on Kihara's advice, Kimura enrolled in the Faculty of Science. By the time of his graduation the war was over, and he joined Kihara who encouraged his study of mathematical problems. During this time, Kimura had no specific duties and took the opportunity on his own to read systematically in mathematical genetics. His mathematics, formidable as it sometimes seems, was mainly self-taught. Life in wartime Japan was miserable, and remained so for some time afterward. Kimura was able to supplement a sparse physical and intellectual diet by visiting his cousin, a quantum physicist who lived in the suburbs and could supply both food and scientific talk. Kimura hoped for a theory of population genetics comparable to that of physics.

In 1949, he joined the staff of the National Institute of Genetics in Mishima, and retained this position for the rest of his life. Thanks to help from some American geneticists studying the effects of the atomic bomb in Hiroshima, he was able to obtain support for graduate study in the USA. After a year at Iowa State College Kimura transferred to the University of Wisconsin in 1954 as the author's student. This also provided an opportunity for daily association with America's most eminent population geneticist, Sewall Wright, who had recently moved to the University of Wisconsin.

Except for his graduate years and several short periods abroad, Kimura spent the remainder of his life in the National Institute of Genetics in Mishima, Japan. Late in his life, he developed amyotrophic lateral sclerosis and died on his 70th birthday, 13 November 1994.

Major Contributions

Kimura's scientific life can be divided into two periods. The first began while he was still a student and continued until 1968. During this time he made major contributions to the mathematical theory of population genetics. In 1968, he introduced his neutral theory of molecular evolution. Although he never stopped making theoretical contributions, his major efforts from this time on were devoted to further developments and defense of the neutral theory.

The mathematical theory of evolution had its heyday in the period roughly from 1920 to 1950. It was almost completely dominated by three men, R.A. Fisher and J.B.S. Haldane in England, UK and Sewall Wright in the US. Kimura became the logical successor. Much of Kimura's work utilized the stochastic equations of the Russian mathematician, A. Kolmogrov. Kimura showed a remarkable inventiveness in solving these difficult equations and applying them creatively to significant evolutionary problems.

Among the problems that Kimura solved are the probability that a new mutant gene will ultimately spread through the population; the number of generations required for this process; if the mutation is lost, the number of generations it persists before loss; the number of individuals that carry a mutation during the time until it is fixed or lost; and the average age of a mutant gene segregating in a population.

At the same time he contributed to many other areas of population genetics theory. These included a comparison of inbreeding systems, showing that systems minimizing the immediate increase in homozygosity are not the best in the long run; a further development of Fisher's 'fundamental theorem of natural selection' with more explicit treatment of gene interactions; a new and influential model of population structure, the 'stepping stone' model, in which migrants are

restricted to neighboring colonies; the efficiency of rank-order selection in changing gene frequencies and removing deleterious mutations from the population.

By 1968 the subject of molecular evolution was in a period of rapid development, which still continues. This was the year of Kimura's bombshell. He argued that the great majority of amino acid and nucleic acid changes are selectively neutral. Instead of natural selection as the main directive force, these changes occur by mutation and whether they persist or are lost is a matter of chance. Remarkably, Kimura's early work on stochastic processes turned out to be preadapted for the study of molecular evolution. He had a set of ready-made tools available, and he proceeded to exploit them with great vigor.

The neutral theory made a number of qualitative and quantitative predictions. Among these was that molecular changes occur at a rate independent of structural and physiological changes; Kimura noted that sharks, whose external form has hardly changed in an enormous time period, have as much molecular variation as rapidly evolving animal species, such as mammals. There were a number of similar predictions. One of the simplest and most remarkable is that the rate of neutral gene substitution in the population is equal to the rate of mutation of this gene per individual. This has permitted predictions of evolutionary rates; departures from these predictions provide evidence for natural selection. Rates that are slower than the neutral expectation can be attributed to 'selective constraint'; that is, the amino acids in this region are so specifically fitted to their function that any replacement doesn't work as well. Thus, essentially all mutations are harmful and are removed by natural selection (sometimes called purifying selection). Several proteins, for example some histones, are in this category. Any change in the molecular structure is harmful. In contrast, regions that evolve faster than the neutral rate are attributed to positive selection. An appreciable number of the mutations are beneficial. One of the best understood examples is the DNA region governing tissue transplants.

The neutral theory has provided a rational basis for the idea of a 'molecular clock' guiding the rate of evolution. The rough constancy of the mutation rates for comparable genes in different organisms – in particular that they are much more stable than the forces of selection – has led to the clock assumption becoming the basis for construction of phylogenetic trees, a field of great activity as molecular data are increasingly used.

At first, Kimura's theory was rejected out of hand by most evolutionists. But gradually, over the years, it has come to be widely accepted. It is now realized that a great deal of the DNA of higher organisms has no known function and that the actual genes constitute a small part of the DNA. At present it is accepted that most nucleic acid substitutions follow the neutral paradigm. As for amino acid changes, the jury is still out. Clearly some changes follow neutral kinetics, others clearly are selected, and the proportions are yet to be sorted out.

An Assessment

Let it be said at the outset that Kimura's work has had its greatest impact on evolution theory rather than on the social and behavioral sciences. His work is very general and is applicable to the whole living world, of which that of greatest interest to social scientists, human evolution, and human behavioral evolution, in particular, is only a part. Molecular evolution has yet to make the impact on human behavioral evolution that it is certain to make one day.

Kimura's greatest contribution has been to impose a stochastic viewpoint on the study of evolution. Beneath surface regularities (and irregularities) of form and function are a multitude of molecular changes, governed by the laws of chance. At present, research in behavioral genetics and evolution is based mainly on deterministic theory. Problems such as separating genetic from environmental effects are usually studied by such means as observing adopted children or identical twins reared apart, and the techniques are usually those derived from analysis of variance. But as evolutionary and population genetics theory becomes further developed and richer, and as the molecular basis of behavioral traits (including those in humans) are better understood, stochastic aspects will play an increasingly important role.

The study of natural selection and adaptation has long had difficulty in formulating clearly testable and falsifiable hypotheses. This has been particularly evident in the abundance of 'just so' stories; because we can think of a plausible reason for a structure or function doesn't necessarily mean that it arose for this reason (although it often has). One attribute of the neutral theory is that it can provide a null hypothesis for testing causes of evolutionary changes. For example, as mentioned above, the neutral theory makes a simple evolutionary rate prediction, against which departures can be measured. Thus far, this kind of reasoning has been used mainly for genes with physiological functions, but as the molecular basis of behavioral changes becomes better understood this kind of analysis will be increasingly applicable.

During his lifetime, Motoo Kimura received virtually every honor for which an evolutionary geneticist is eligible. In addition to numerous honors both in Japan and elsewhere, he was a foreign member of the United States National Academy of Sciences, the Royal Society of London, and the Chevalier de L'Ordre National du Mérite in France. He received honorary doctorates from the Universities of Chicago and Wisconsin.

Kimura's lasting impact is twofold. The first, best appreciated by population geneticists, is his enrichment of population genetic and evolutionary theory, especially as these are influenced by stochastic processes. The second, appreciated by a much larger audience, is his discovery of the enormous role that random processes play in molecular evolution. Kimura never denied the importance of Darwinian natural selection as the main evolutionary force shaping form and function, but beneath this, he emphasized, is an enormous play of random changes at the molecular level. In addition to Darwin's 'survival of the fittest,' he added the slogan, 'survival of the luckiest.'

Kin Selection

Andy Gardner, University of St Andrews, St Andrews, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The theory of kin selection is the foundation for the study of social evolution. Here I discuss the historical origins of the theory, provide a mathematical overview, review the various mechanisms that give rise to kin selection, and explain its relevance to the understanding of eusociality.

The Origins of Kin Selection

The basic idea of kin selection was formulated by Charles Darwin, in *The Origin of Species* (Darwin, 1859; *see* Darwinism). It arose as the solution to a puzzle posed by sterile workers in social insect colonies; specifically, how to explain the striking adaptations of these individuals, given that they cannot reproduce and hence appear to be beyond the reach of natural selection. Darwin realized that this puzzle is similar to a problem faced by farmers who rear cattle for their meat. After slaughtering an animal, preparing the meat, and finally discovering that it is particularly delicious, the farmer is unable to breed from the slaughtered individual to ensure that subsequent generations of the herd will inherit the superior meat. However, he/she can breed from the slaughtered individual's close relatives who, on account of their co-ancestry, are likely to share the heritable tendency for delicious meat. Darwin suggested that something similar happens in the social insects. If a variant worker behavior or morphology arises that provides a reproductive benefit to the individual's fertile family members then, because those family members have a strong likelihood of sharing the same heritable tendency, it may be preserved for posterity by the action of natural selection.

Later, R.A. Fisher provided a kin selection explanation for the evolution of distastefulness in gregarious insect larvae in *The Genetical Theory of Natural Selection* (Fisher, 1930). He suggested that, although distastefulness provides no benefit to a predated larva, it may dissuade the predator from eating the larva's siblings. Fisher remarked that the ensuing selective benefit is only half as great as it would be had the individual herself avoided predation, and this appears to be the first use of a coefficient of relatedness to translate fitness effects for relatives into a selective benefit for a focal actor. However, Fisher did not elaborate the principle for more distant degrees of relationship. And he explicitly neglected such 'indirect effects' in the derivation of his fundamental theorem of natural selection, which he used as justification for the view that natural selection leads organisms to appear designed to maximize their personal reproductive success. In 1955, in a popular science article, J.B.S. Haldane gave a verbal account of how selection would operate on a rare gene that made its carrier jump into a river to save a drowning relative, showing that the gene could only be selectively favored if the degree of relationship were sufficiently close (Haldane, 1955). However, he seems not to have appreciated that this principle could be used to understand social evolution more generally.

Thus, it fell to W.D. Hamilton to develop and usefully apply a proper mathematical theory of kin selection, more than a century after Darwin had first formulated the idea. As an undergraduate at the University of Cambridge in the 1950s, Hamilton had been dismayed by the rampant 'for the good of the species' thinking that had come to dominate evolutionary biology in general and the study of social behavior in particular. So he took up the mantle of kin selection where Fisher had left it, focusing his doctoral studies upon the genetical evolution of altruistic behavior. In a series of articles published over 10 years during the 1960s and 1970s (Hamilton, 1963, 1964, 1967, 1970, 1972), Hamilton laid the theoretical foundations of kin selection, devised a classification of social behaviors, derived a general statement of how direct and indirect fitness effects jointly determine the response to natural selection, showed that this leads organisms to appear designed to maximize their inclusive fitness rather than their personal fitness, and applied this understanding to make seminal contributions to the topics of altruism, sex allocation, and eusociality. Spurred by Hamilton's work, John Maynard Smith coined the term 'kin selection' (Maynard Smith, 1964), and Eric Charnov immortalized Hamilton's contribution by naming the core mathematical result of kin selection theory 'Hamilton's rule' (Charnov, 1977). The theory of kin selection now provides the foundation for the study of social evolution (Frank, 1998).

The Genetical Theory of Kin Selection

The canonical elucidation of kin selection theory takes Price's (1970) equation of natural selection as its starting point (e.g., Hamilton, 1970). The following exposition owes heavily to Queller (1992) and is more fully developed by Gardner et al. (2011). Price's equation encapsulates the action of natural selection as the part of genetic change that is ascribable to the differential fitness of individuals:

$$\Delta_{\mathrm{NS}}E(g) = \mathrm{Cov}(v, g). \qquad [1]$$

This states that the change in the population average (or expectation, E) of any genetical character that owes to the action of natural selection is equal to the covariance (Cov) of relative fitness (v) and genetical character (g) across all the individuals in the population. Here, the genetical character

may represent the frequency of a particular gene in the individual's genome (in which case $E(g)$ is the population frequency of that gene), the heritable component of any phenotypic trait of interest (i.e., a genetic 'breeding' value), or any other weighted sum of genic values. That is, if individuals with a greater genetical character value tend to have higher fitness, then the covariance is positive ($\mathrm{Cov}(v, g) > 0$) and natural selection acts to favor an increase in average character value ($\Delta_{\mathrm{NS}}E(g) > 0$). Whereas, if individuals with a greater genetical character value tend to have lower fitness, then the covariance is negative ($\mathrm{Cov}(v, g) < 0$) and natural selection acts to favor a decrease in the average character value ($\Delta_{\mathrm{NS}}E(g) < 0$). If there is no tendency for individuals with a greater genetical character value to have higher or lower fitness, then the covariance is zero ($\mathrm{Cov}(v, g) = 0$), and natural selection favors neither an increase nor a decrease in the average character value ($\Delta_{\mathrm{NS}}E(g) = 0$).

Assuming that there is some heritable variance in the population (i.e., $\mathrm{Var}(g) > 0$) then, without loss of generality, one can write $\mathrm{Cov}(v, g) = \beta(v, g)\mathrm{Var}(g)$, where $\beta(v, g) \equiv \mathrm{Cov}(v, g)/\mathrm{Var}(g)$. This coefficient $\beta(v, g)$ turns out to have a useful interpretation: if one were to make a plot of relative fitness (v) against genetic character (g) for all the individuals in the population, then $\beta(v, g)$ is equal to the slope of the straight line $E(v|g) = E(v) + \beta(v, g)\,(g - E(g))$ fitted through these (v, g) data by the method of least squares (Figure 1(a)). Since variances are non-negative, the condition for natural selection to favor an increase in average character value ($\mathrm{Cov}(v, g) > 0$) may be written as:

$$\beta(v, g) > 0 \qquad [2]$$

Note that I have not assumed that there is a straight-line relationship between genes and fitness in the population. Indeed, there may be an arbitrarily complex relationship between genes and fitness, and the least-squares fit may fail to capture lots of this complexity (Figure 1(a)). However, it is only the least-squares fit that natural selection cares about. That is, natural selection favors an increase in the average character value if and only if the slope of the least-squares linear regression is positive, and this translates into an actual response to selection in proportion to the heritable variance that is present in the population.

This association between genetic value and fitness is statistical and need not reflect a direct causal relationship. For example, if we consider that the genetic character leads the individual to enact altruism toward her neighbor, then the direct impact of the character on her own fitness will be negative, but she may enjoy an indirect benefit owing to her neighbor also carrying the gene and directing altruistic behavior back toward her. The overall slope of relative fitness against genetic character can be partitioned into these separate direct and indirect effects using multiregression methods. That is, instead of fitting a straight line through two dimensional data, as was described earlier, the idea is to fit a plane $E(v|g, g') = E(v) + \beta(v, g|g')\,(g - E(g)) + \beta(v, g'|g)\,(g' - E(g'))$ through the three-dimensional data set (v, g, g'), where g' denotes the genetic character of the focal individual's neighbor (Figure 1(b)). This leads to the multiregression partition:

$$\beta(v, g) = \beta(v, g|g') + \beta(v, g'|g)\,\beta(g', g). \qquad [3]$$

Considering an altruistic trait, the impact of the individual's character value (g) upon her own fitness (v), holding fixed the character value of her neighbor (g'), defines the cost of altruism for the actor, i.e., $\beta(v, g|g') \equiv -c$. The impact of the neighbor's character value (g') upon the focal individual's own fitness (v), holding fixed her own character value (g), defines the benefit of altruism for the recipient, i.e., $\beta(v, g'|g) \equiv b$. Finally, the association between the genetic character values of the focal individual (g) and her neighbor (g') defines the kin selection coefficient of relatedness, i.e., $\beta(g', g) \equiv r$. Hence, from eqn [3], the condition for natural selection to favor an increase in altruism – or, indeed, any genetic character of interest – is:

$$-c + br > 0, \qquad [4]$$

which is Hamilton's rule of kin selection. This formally separates the direct fitness effect of a character ($-c$) from the indirect

Figure 1 The genetical theory of kin selection. (a) Natural selection favors any heritable trait that is positively associated with fitness ($\beta(v, g) > 0$). (b) This association can be broken down into the direct impact of the trait on its bearer's fitness ($\beta(v, g|g')$) and the indirect impact of the trait on its bearer's fitness ($\beta(v, g'|g) \times \beta(g', g)$).

fitness effect of that character (rb). The part of natural selection corresponding to direct fitness effects may be termed 'direct selection,' and the part that corresponds to indirect fitness effects may be termed 'indirect selection' or 'kin selection.' That is, kin selection is a part of natural selection, driven by differences in individual fitness, rather than an additional evolutionary process.

In the above derivation, I have assumed that the focal individual has only a single social partner. However, the same methods are readily extended to consider multiple social partners, acting in a variety of roles. This yields a Hamilton's rule of the form $-c + \Sigma_{i \in I}\, b_i\, r_i$, where b_i and r_i are the benefit and relatedness, respectively, corresponding to the individual's ith social partner (Grafen, 2006). I have also assumed that the focal individual and her social partner are interchangeable. That is, they are exactly equivalent in all ways except for their genetic character values. More generally, social partners may belong to different classes, such as male and female or young and old or queen and worker. However, kin selection methods are also readily applied to such class structured populations (Taylor, 1990). Note that I have made no assumption that genes for altruism are additive in their action. There may be any degree of dominance within loci, epistasis between loci, synergy between individuals and frequency dependence at the population level and Hamilton's rule still holds. Recurring claims that Hamilton's rule breaks down in these scenarios are based upon a confusion between the additivity of a linear regression model versus the additivity of an evolutionary genetics model (reviewed by Gardner et al., 2011).

Here, I have focused on altruism, but Hamilton's rule applies when any heritable trait is favored by natural selection. Social behaviors are classified according to their impact on the fitness of the actor and the recipient (Table 1): altruistic behaviors decrease the fitness of the actor ($c > 0$) and increase the fitness of the recipient ($b > 0$); selfish behaviors increase the fitness of the actor ($c < 0$) and decrease the fitness of the recipient ($b < 0$); mutually beneficial behaviors increase the fitness of both the actor ($c < 0$) and the recipient ($b > 0$); and spiteful behaviors decrease the fitness of both the actor ($c > 0$) and the recipient ($b < 0$). In each case, the condition for natural selection to favor the social behavior is $-c + br > 0$. Note that spiteful behavior ($b < 0$ and $c > 0$) is only favored if there is negative relatedness between actor and recipient ($r < 0$, such that $-c + br > 0$). Negative relatedness sounds unusual, but simply means that the actor and recipient are less related than average (Hamilton, 1970). Nonsocial behaviors are those that do not have fitness consequences for individuals other than the actor ($b = 0$), and hence are favored if they improve the fitness of the actor ($c < 0$) and are disfavored if they reduce the fitness of the actor ($c > 0$).

The above derivation of Hamilton's rule has taken the 'personal fitness' or 'neighbor-modulated fitness' approach to kin selection (Figure 2). This considers the impact of an individual's own genetic character (g) and that of her social partner (g') upon her own fitness (v). An alternative – but exactly equivalent – approach is the 'inclusive fitness' approach, which considers the impact of an individual's own genetic character (g) upon her own fitness (v) and the fitness of her social partner (v'; Figure 2). The only difference between these two approaches is that the benefit term, conceptualized as $b = \beta(v, g'|g)$ under the personal fitness view, is reconceptualized as $b = \beta(v', g|g')$ under the inclusive fitness view. Thus, the response to selection may be written as $\beta(v, g|g') + \beta(v', g|g')r = \beta(v + v'r, g|g')$. This describes the partial effect of the individual's own genetic character (g) upon the relatedness-weighted sum of the individual's relatives' fitnesses ($v + v'r$), i.e., the impact that the individual has upon her own inclusive fitness.

Table 1 Classification of social behaviors

		Impact upon recipient	
Impact upon actor		+	–
	+	Mutual benefit	Selfishness
	–	Altruism	Spite

Behaviors that increase the fitness of both actor and recipient (+/+) are termed *mutually beneficial*; behaviors that increase the fitness of the actor and decrease the fitness of the recipient (+/–) are termed *selfish*; behaviors that decrease the fitness of the actor and increase the fitness of the recipient (–/+) are termed *altruistic*; and behaviors that decrease the fitness of both actor and recipient (–/–) are termed *spiteful*. See West et al. (2007) for more discussion.

Figure 2 Personal and inclusive fitness. Personal (or neighbor-modulated) fitness describes a focal individual's lifetime reproductive success (unshaded offspring), some of which may be attributed to the action of the individual's own genes (unshaded hands), and some of which may be attributed to the action of the genes carried by the individual's social partners (shaded hands). A necessary and sufficient condition for genes to be favored by natural selection is that they are positively associated with personal fitness. However, individuals do not behave as if they are trying to maximize their personal fitness, because they do not have complete control over this quantity. Inclusive fitness describes the impact that a focal individual's genes (unshaded hands) have on her own fitness (unshaded offspring) and the fitness of her genetic relatives (shaded offspring), each increment or decrement being weighted by the coefficient of relatedness between the individual and her recipient. A necessary and sufficient condition for genes to be favored by natural selection is that they are positively associated with inclusive fitness. Moreover, individuals do behave as if they are trying to maximize their inclusive fitness, because they have complete control over this quantity.

Inclusive Fitness

The dynamics of natural selection – operating via direct and indirect (kin selected) effects – can be understood either in terms of personal fitness or in terms of inclusive fitness. These two approaches are exactly equivalent and yield the same predictions. However, the adaptive design that emerges from the action of natural selection can only be understood in terms of inclusive fitness. The organism is not generally adapted to maximize her personal fitness, because – in the context of social interactions – she does not have full control over this quantity. However, she is adapted to maximize her inclusive fitness, which is under her sole control, the effects of her social partners having been explicitly stripped away. Consequently, inclusive fitness is a crucial concept in the study of Darwinian adaptation (*see* Adaptation, Fitness, and Evolution). The formal connection between the dynamics of natural selection and the optimization of inclusive fitness has been shown by Grafen (2006).

This point is best explained with an illustration. Consider a gene that makes an insect worker lay fewer eggs and work harder to improve the reproductive success of her queen. From a personal fitness approach we would say that sometimes the gene will be present in a worker, in which case it will be associated with reduced fitness, because it makes her lay fewer eggs; but sometimes the gene will be present in a queen, in which case it will be associated with increased fitness, because the workers in the queen's colony will also tend to carry the gene, which makes them work harder. Consequently, the gene for worker altruism will be favored if the former direct effect is outweighed by the latter indirect effect. However, we cannot regard the insect worker as striving to maximize her personal fitness, as this would never allow for worker altruism to evolve. Instead, we can take an inclusive fitness approach and say that altruism enacted by the worker reduces her direct fitness, by making her lay fewer eggs; but it also improves her indirect fitness as a consequence of increasing the reproductive success of the queen; and, consequently, worker altruism is favored if the former direct effect is outweighed by the latter indirect effect. Crucially, the worker can be regarded as striving to maximize her inclusive fitness, as it is under her complete control.

Often, the personal fitness approach is the easier option when the aim is simply to capture the dynamics of natural selection in a mathematical model. However, by emphasizing an actor and the causal impact that her social behavior has upon the reproductive success of her social partners, the inclusive fitness approach is more useful for empirical research in behavioral ecology. Moreover, because humans are naturally better at reasoning about agents and strategies than about the dynamics of gene frequencies, the inclusive fitness approach – which yields a simple maximizing agent interpretation – provides a powerful way of thinking about social evolution. The notion of an agent with an agenda is implicit within the intentional language employed by evolutionary biologists: selfishness, altruism, conflicts of interest, etc. For these reasons, the inclusive fitness approach to kin selection has dominated the empirical study of social evolution.

Mechanisms of Kin Selection

Kin selection occurs whenever there is a genetic association between the actor and the recipients of her social behavior. Hamilton (1964) suggested three basic mechanisms for ensuring such a genetic association: population viscosity; kin recognition; and the greenbeard effect (Figure 3).

First, population viscosity occurs when individuals do not disperse far from their place of origin, so that neighboring individuals tend to be closely related, and hence even indiscriminate social behavior can lead to kin selection (Figure 3(a)). Because this requires no special cognition or recognition mechanism, population viscosity has been suggested to provide a very general explanation for cooperative behavior. However, a problem with this idea is that viscosity may also be associated with intense local competition for resources, which can inhibit the evolution of cooperative behavior. In fact, in the simplest models of viscous populations the relatedness-enhancing and competition-enhancing effects of reduced dispersal exactly cancel so that there is no overall impact of the rate of dispersal on the evolution of cooperation (Taylor, 1992). This surprising result has generated a great deal of theoretical interest in exploring factors that act to decouple the relatedness and competition consequences of dispersal, so that cooperation can evolve in viscous populations.

One such factor is budding dispersal. If individuals disperse in groups, alongside social partners, then they may maintain high relatedness with their neighbors while also enjoying the competition-relaxation benefits of dispersal. This idea has been tested empirically, using experimental evolution of

Figure 3 Mechanisms of kin selection. (a) Population viscosity: if individuals do not move far during their lifetime, then they will tend to be surrounded by kin (shaded), and hence even indiscriminate social behavior will give rise to kin selection. (b) Kin recognition: if individuals use cues that carry information about kinship to mediate their social behavior, such as remembering with whom they shared a nest (shaded) and acting altruistically toward those individuals, then this will give rise to kin selection. (c) Greenbeard effect: if the gene controlling social behavior is associated with a phenotypic marker, such as a beard, then carriers of the gene can identify which of their social partners also carry copies, independently of whether or not these social partners are kin (shaded).

Pseudomonas aeruginosa bacteria. In iron-limited medium, bacterial cells may release iron-scavenging molecules called siderophores that bind iron and facilitate its uptake by cells. However, the cell that takes up the bound iron need not be the cell that manufactured and released the siderophore, so siderophore production is a form of public-goods cooperation and cheating cells that do not produce siderophores may free-ride on the cooperation of the other cells in the medium. Kummerli et al. (2009) varied the pattern and rate of dispersal of cells between flasks of medium and showed that, while cooperation was disfavored under both high and low individual dispersal, it was favored under budding dispersal.

Second, kin selection may also occur when individuals use environmental or genetic cues to recognize which of their social partners are their genealogical kin and adjust their social behavior according to this information (Figure 3(b)). Environmental kin recognition occurs when an individual makes use of an environmental cue that is associated with her having greater kinship to her social partners. For example, the rule 'behave altruistically toward individuals who are in my nest, and behave aggressively toward individuals who are not in my nest' uses the position of the recipient relative to the individual's own nest as a proxy for degree of kinship. In contrast, genetic kin recognition occurs when an individual makes use of a genetic cue. For example, if blue eyes were relatively rare in the population, then it is likely that two neighbors who shared blue eyes would do so because they were genealogically close kin, rather than simply by chance. Consequently, individuals may be favored to behave altruistically toward those neighbors whom they most closely resemble.

However, genetic kin recognition appears to be inherently unstable. This is because, while only relatively rare genetic markers provide a good indicator of genealogical closeness, common genetic markers may enjoy a selective advantage owing to their carriers being more often identified as kin and receiving benefits of altruism. Hence, the polymorphism at marker loci that is required for genetic kin recognition to work may be eroded by natural selection, until every individual carries the same alleles, which no longer give any information about genealogical kinship (Crozier, 1986). This may explain why genetic kin recognition is relatively rare in the natural world. One possibility for maintaining genetic kin recognition is if the genetic marker loci mediate host–parasite interaction, as this is a potent source of balancing selection that can help to maintain rare alleles. This may explain why genetic kin recognition, when it does occur, appears to be based on immune-system genes such as the multihistocompatibility complex in humans (Wedekind et al., 1995) and extraembryonic-membrane genes in parasitoid wasps (Giron and Strand, 2004).

Third, the greenbeard effect is similar to genetic kin recognition, but occurs when the same gene (or two closely linked genes) encodes both the marker and the social behavior (Figure 3(c)). The idea here is that two individuals who share a genetic marker in common may also share genes for social behavior that are linked to that marker, irrespective of whether they are genealogically close kin. The greenbeard mechanism was devised by Hamilton (1964) as a thought experiment to illustrate that genetic similarity, and not genealogical kinship per se, is the key to kin selection. The name was coined by Dawkins (1976), who gave a hypothetical example of a gene that causes its carrier to grow a green beard and to act altruistically toward other individuals with green beards. However, empirical examples have been found in the natural world. For example, bacteriocins are toxins produced by bacteria, often at great cost to the producer cell, that poison neighboring cells. The bacteriocin gene is tightly linked to a gene for immunity to that bacteriocin (they are often carried together on a plasmid), and so other carriers of the bacteriocin gene survive the killing and benefit from reduced competition for resources (Gardner and West, 2010). Greenbeards are susceptible to invasion by 'falsebeards,' that enjoy the benefits of bearing a beard but without paying the costs of the social behavior (Gardner and West, 2010). For example, a bacterium that enjoys immunity to bacteriocins without committing itself to the costs of bacteriocin production. Such falsebeards are readily created by sex and recombination between beard and behavior loci, and this may explain why most empirical examples of greenbeards are found in the asexual world of microbes.

Kin Selection and Eusociality

Obligate eusociality is a permanent division of reproductive labor, whereby both reproductive and helper castes are required for totipotency. This system of biological organization is known only in the social hymenoptera (ants, wasps, and bees) and the social cockroaches (termites). The problem of eusociality is to explain why individuals of the helper caste have evolved to give up any chance of future reproductive success in order to serve the needs of their reproductive colony mates. This is the most striking example of altruistic behavior in the natural world and has consequently received much attention from kin selection researchers.

Historically, most attention has been given to the 'haplodiploidy hypothesis' for eusociality. Most of the origins of obligate eusociality have occurred in the social Hymenoptera, a group that is noted for its haplodiploid mode of inheritance. These organisms produce diploid daughters sexually, with one genome being contributed from the mother and one from the father. But they produce haploid sons asexually, from unfertilized eggs. Hamilton (1964, 1972) famously suggested that the apparent predisposition for haplodiploid organisms to eusociality owes to the inflated relatedness between full sisters that emerges under this mode of inheritance. Under both diploidy and haplodiploidy, the relatedness of a female to her daughter is one half ($r = 1/2$), but whereas the relatedness between sisters under diploidy is also one half ($r = 1/2$) the relatedness between sisters under haplodiploidy is three quarters ($r = 3/4$). Hence, while females in diploid populations are ambivalent over whether to rear a sister or a daughter, females in haplodiploid populations prefer to rear sisters over daughters, and this potentially paves the way for the evolution of eusociality.

However, this argument does not really work. Hamilton (1964, 1972) was aware that the relatedness between sister and brother is correspondingly lower under haplodiploidy, and Trivers and Hare (1976) pointed out that this actually cancels any benefit of rearing siblings (sisters and brothers)

rather than own offspring (daughters and sons), assuming an even sex ratio. Craig (1979) subsequently showed that even a female-biased sex ratio does not resolve this problem, as the increased relatedness to siblings (mostly sisters) is exactly countered by the increased reproductive value of males (which is higher, owing to the rarer-sex effect, in a population with a female-biased sex ratio). Haplodiploidy can be made to promote altruistic sib-rearing if there are 'split sex ratios,' whereby some colonies are relatively female biased and others are relatively male biased (Grafen, 1986), but it can also be made to inhibit altruistic sib-rearing, and in most cases its impact is meager (Gardner et al., 2012).

Instead, the key to eusociality appears to be strict lifetime monogamy, which ensures that maternal siblings are full siblings, and hence – on average – as related to the actor as are her own offspring (Boomsma, 2009). That is, it is not necessary for relatedness of siblings to exceed that of offspring, but only that relatedness of siblings match that of offspring, such that any slight efficiency benefit of sib-rearing is sufficient to provide a selective advantage for eusociality. Although not all eusocial organisms are strictly monogamous – the highly polyandrous honeybee providing a striking counterexample – phylogenetic analysis reveals that strict lifetime monogamy is the ancestral state for all eusocial hymenoptera and was the mating system in which eusociality always initially arose (Hughes et al., 2008). The predisposition for the hymenoptera to evolve eusociality may simply be due to their ancestral sperm-storage ability, which enables a singly mated female to produce multiple batches of offspring without needing to remate. Moreover, the monogamy hypothesis also explains why termites have evolved eusociality (their societies are founded by a monogamous mating pair), despite their diploid mode of inheritance.

Summary

Darwin formulated the concept of kin selection in *The Origin of Species*. More than a century later, Hamilton developed a mathematical theory of kin selection, and showed that natural selection leads organisms to appear designed to maximize their inclusive fitness. Hamilton's rule of kin selection emerges as a simple partition of natural selection into its direct and indirect components and is as general as the genetical theory of kin selection itself. There are three major mechanisms by which kin selection operates: population viscosity, kin recognition, and the greenbeard effect. Kin selection is the key to understanding altruistic behavior and the evolution of eusociality.

Abstract

Intermittent application of brief trains of electrical stimulation to focal areas of the brain triggers epileptiform discharge (afterdischarges) and the gradual development of behavioral seizures, a phenomenon known as kindling. Because the intensity of the electrical stimulation is not altered, kindling must be due to a change in the responsiveness of the nervous system itself. Thus kindling results in an extreme form of sensitization, to the extent that the kindled brain is inordinately responsive to a variety of potential convulsants. Another important characteristic of kindling is that the increase in the nervous system's susceptibility to seizures is extraordinarily long-lasting and may be considered permanent. Moreover, kindling allows a high degree of experimental control, as the researcher can target any nuclei in the brain and apply stimulation at will. Kindling has proven to be one of the most robust, reliable, and dramatic forms of neural plasticity yet described, and over the past half century, it has attracted an enormous amount of experimental attention.

While Graham Goddard's seminal paper in 1967 is rightly credited as the first systematic description of the kindling phenomenon there were several earlier observations of kindling-like phenomenon. Descriptions by Watanabe in 1936, by Whieldon and Van Harreveld in 1950, from Jose Delgado's laboratory at Yale in the late 1950s and early 1960s all preceded Goddard. But it was Graham Goddard who first fully appreciated, named, and then with the help, in the early days, of several others, including Ron Racine, Dan McIntyre, Juhn Wada, John Pinel, Mac Burnham, Michael Corcoran, Peter Cain, and Bob Adamec, effectively promoted and explored kindling.

The Discovery of Kindling

There are several noteworthy discoveries in the history of neuroscience that arose from serendipitous observations and the discovery of kindling was one such observation that began from research on an entirely different problem. Graham Goddard's doctoral research in the early 1960s was concerned with the effects of electrical stimulation of the amygdala on conditioning in rats. Due to an equipment malfunction, Goddard accidentally delivered repeated trains of fairly high-intensity stimulation to the amygdala of some rats, one of which developed seizures after a few repetitions. The rat continued to display seizures even after the equipment had been repaired and low-intensity stimulation was delivered. Goddard realized that this might be significant when he found that the low-intensity stimulation given to experimentally naive rats did not cause seizures. In other words, it was the *repeated application* of stimulation that led to the elicitation of seizures, not the stimulation itself. In an independent and elegant series of experiments, Ronald Racine (1972a,b) carefully monitored electroencephalogram activity during kindling and convincingly demonstrated that stimulation has to elicit an afterdischarge (AD) in order to kindle seizures. Goddard further surmised that the brain itself might have been changing in response to the repeated application of stimulation, and that this phenomenon might in turn have something to do with the mechanisms of learning. It is worth noting the Goddard's view of the emerging phenomenon was that it could give insight into the normal functioning of the brain. This is important because the initial questions that he formulated where predicated on the notion of discovering a relation between kindling and normal learning and memory, rather than kindling as a model of seizures and epilepsy.

The Properties of Kindling

In order for the phenomenon to potentially be related to learning and memory, it should show the following properties: Different areas should have different susceptibilities; the effect should be persistent; it should be found in all mammals; and intermittent stimulation should be more effective than massed stimulation. Furthermore, the phenomenon should not depend on the electrical stimulation itself, and it should not be due to damage cause by the electrode or the passing of current.

Differential Susceptibility of Brain Areas

Kindling rate is operationally defined as the number of stimulations delivered to brain that results in some clearly defined end point such as the first fully generalized (stage 5) seizure. Within rat brain there is a relationship between the structure being kindled and its kindling rate. The following forebrain areas are ordered from slowest kindling rate to fastest kindling rate: dorsal hippocampus, ventral hippocampus, amygdala, piriform cortex, and perirhinal cortex. Many more brain structures than those listed here have been kindled and all have shown the phenomenon except one; the cerebellum. Although many of us have tried, it seems that the cerebellum is incapable of generating an epileptiform discharge. Note that kindling rate, as defined above, is based on a behavioral seizure and that means the elicited AD must spread to motor circuits and

ultimately to the spinal cord and alpha motor neurons. Thus, kindling rate is a function of the propagation of ADs from the site of stimulation to other structures. Kindling rate is a different phenomenon from seizure susceptibility or AD threshold, which is defined as the minimal amount of current that can elicit an AD. The hippocampus appears to have the lowest AD threshold but takes a large number of stimulations to kindle. Thus different brain areas have both different kindling rates and seizure thresholds that appear to be independent from each other.

Persistence

Several publications have documented that kindling, like learning, is highly persistent (Wada et al., 1974). Rats that have been kindled in the hippocampus or amygdala rested for long periods of time (e.g., 24 weeks) and then rekindled showed remarkable savings. Rats typically displayed much shorter AD durations and less-severe behavioral seizures on the first rekindling stimulation compared to the response to the last stimulation before the rest period. However, they rapidly rekindle and only a few stimulations are required before they displayed the behavioral end point they achieved before the rest interval (Dennison et al., 1995). The effects of kindling are highly persistent compared to the life span of the animal.

Generalizability

Kindling has been demonstrated in all species studied to date. Seizures can be kindled in lizards, frogs, mice, gerbils, rats, rabbits, guinea pigs, cats, dogs, squirrel monkeys, rhesus monkeys, and several species of baboon. Thus kindling is a very robust and seemingly universal phenomenon in all vertebrates tested. But has kindling occurred in humans?

There are two published accounts of kindling in people. Sramka et al. (1977) described the case of a 47-year-old woman who carried depth electrodes located in three structures of the left thalamus and was stimulated daily to relieve pain. During the third week of stimulation, she developed spontaneous mild movements in the right half of her face and parts of her right hand. Although the electrodes were removed, she continued to have seizures and paroxysmal brain activity, and the seizures became secondarily generalized. Monroe in 1982 also clearly described kindling in a person. On the face of it, these data suggest that the human brain is indeed susceptible to kindling. So why are there not more reports of kindling in people? It is, of course, possible that physicians have observed kindling after electrical stimulation of the human brain but have refrained from reporting it, for fear of prosecution. In confirmation of this possibility, Dan McIntyre has described private conversations with neurologists who stated that they have unintentionally kindled seizures with stimulation via depth electrodes in some patients.

What might occur more obviously in some populations of people with epilepsy is an intensification of ictal phenomena that could be due to kindling-like events or to the neurobiological mechanisms underlying kindling. Neurologists have argued that the progressive increases in ictal phenomena observed in patients with tumor-related seizures can be attributed to a kindling-like effect. Similarly, withdrawal seizures can intensify with repeated episodes of detoxification from ethanol in humans, an observation interpreted as a kindling effect. In balance, we think it is a certainty that a kindling-like process occurs in the human brain.

Stimulation Interval

Goddard et al. (1969) were also concerned with identifying the optimal stimulation schedule for kindling seizures, and they found that kindling was unlikely with continuous stimulation or stimulation presented at interstimulation intervals below 20 min, whereas the high probability of kindling did not vary at interstimulation intervals of 8 h to 7 days. That is, continuous or too frequent stimulation in adult rats either fails to kindle seizures or results in a long-lasting decrease in seizure susceptibility that interferes with subsequent kindling. The cardinal consideration is that stimulation not be applied at too short an interval; otherwise kindling will fail (Racine et al., 1973).

Brain Damage

Normal learning and memory obviously does not result from the irritative effects of deposited metals from electrodes or outright tissue damage, so it was important for the early kindlers to show that electrode deposition and/or damage did not result from repeated stimulations. There was prior work demonstrating that seizures could be triggered by electrolysis of metallic ions into brain tissue, and it is likely that some deposition of ions occurs even with the balanced waveforms used for kindling. Might not kindling then be due simply to local irritative effects produced by passage of current through metal electrodes? Perhaps the most convincing evidence against a role for irritative effects is found in the observation that kindling of one brain site results in *transfer* of seizure susceptibility to a second brain site. This is measured by a significant facilitation in the rate of secondary-site kindling as compared to naive controls. If kindling is due solely to induction of an irritative focus restricted to the primary site of stimulation, it is unclear how this could drive epileptiform events outside the focus and result in the development of behavioral seizures, which presumably reflect activity produced in part in spinal circuits. Thus, transfer clearly indicates that kindling involves development of multiple areas of enhanced epileptogenicity, and this development must depend, in part at least, on synaptic transmission.

Unfortunately trying *not* to find brain damage is akin to testing the null hypothesis and as all students of research methodology know an inadequate sample size and/or poor measurement technique will ensure that no difference between comparison groups is found. With respect to damage, it has been shown that kindled seizures do result in neuronal loss (Cavazos et al., 1994), astrocyte hypertrophy (Khurgel and Ivy, 1996), and other indies that the brain is compromised. Since epilepsy, but not learning is associated with these sorts of changes this leads us to consider kindling as a model of seizures and epilepsy.

Kindling as a Model for Seizures and Epileptogenesis

The generality of kindling raises two important questions: Does kindling capture relevant features of the clinical epilepsies – is kindling a valid 'animal model' of epilepsy?

Kindling provides strong homology – an animal model – for many aspects of seizures and epilepsy – but just which aspects? This is a complex question, because kindling may be used in a multiple ways. Because kindling is both a phenomenon and a technique, we summarize here the phenomenological properties as well as the technical aspects with respect to the clinical condition. We suggest that kindling can be used to model: (1) the *creation* of a seizure focus, (2) the *occurrence* of focal and secondarily generalized seizures (ictal behaviors), (3) either the *progression* in severity of seizures (epileptogenesis) or the *stability* of seizures over time, (4) focal seizures of *unknown cause*, (5) *multiple* seizure generators, (6) pharmacoresistance and conditioned tolerance, and (7) the consequences of multiple seizures, including cognitive dysfunction, personality disturbances, and psychoses (interictal behaviors).

Creation of a Seizure Focus

In the case of posttraumatic epilepsy, tissue that was presumably once normal becomes disrupted in a manner that eventually gives rise to spontaneous seizures. It is evidently not the case that the acute reactive ictal events that occur during the immediate posttraumatic period necessarily cause the appearance of a chronic epileptic condition. Furthermore, the risk factors for reactive seizures are different from those for chronic epilepsy. Thus, some other mechanism, working over months or years, and causing some structural reorganization of the injured tissue eventually results in spontaneous seizures. In the experimentally naive animal, direct application of electrical stimulation that does not initially give rise to an AD can, if it is repeated over several sessions, eventually come to give rise to an AD (Flynn and Teskey, 2007). In this way repeated subthreshold stimulation could model the 'irritation' and lower seizure threshold until seizures emerge.

The Occurrence of Focal and Secondarily Generalized Seizures

Kindling is perhaps most obviously a model for seizures, because seizures can be evoked following brief trains of suprathreshold electrical stimulation. In patients with epilepsy, where activity is generated from a particular focus, the seizures or convulsions are remarkably similar to those shown by the kindled animal stimulated in the same site. Manifestations of both tonic and clonic behaviors are readily induced in the kindled animal. Hence, the initial seizures kindled from amygdaloid or cortical loci resemble either simple partial or complex partial attacks (Racine's stages 1–3), and later seizures that secondarily generalize resemble tonic–clonic attacks (Racine's stages 4 and 5) (Racine, 1972b).

The Progression in Severity of Seizures (Epileptogenesis)

The progression of seizure severity in epileptic populations is somewhat controversial because the widespread use of anticonvulsant drugs prevents an uncontaminated examination of the phenomenon. However, before the introduction of anticonvulsant drugs, it was observed that as seizures recurred there was an increasing tendency for minor attacks to lead to major ones and for the interval between attacks to decrease. The famous quote "seizures beget more seizures" captures this general tendency. It is probably the case that certain subpopulations of people with epilepsy tend to show seizure progression, whereas other subpopulations tend to show stability in seizure severity. The aspects of kindling that model seizure progression are as follows: (1) the unambiguous progression of electrographic and seizure severity with repeated stimulations; (2) the occurrence of focal seizures in one hemisphere leading to the development of independent discharge at sites in the contralateral hemisphere; (3) increased transsynaptic excitability; and (4) the increase in neuronal burst-firing.

Note that kindled seizures are typically elicited, whereas epileptic seizures in patients occur spontaneously. However, some species of animal (e.g., rats, gerbils, cats, dogs, baboons) can be kindled to the point where they exhibit spontaneous seizures, and this contradicts the argument that kindling lacks relevance because the seizures are induced and not spontaneous. Furthermore, the spontaneous seizures that patients express, although not induced by trains of electrical stimulation, are induced by *some* stimulus, probably internal but possibly external (although not obvious). In this way, kindling can be thought to model focal seizures of unknown cause.

Multiple Seizure Generators

The technique of concurrent multiple-site kindling leads to a more rapid progression and greater seizure severity, and this is probably related to the higher incidence of seizures, more severe seizures, and more frequent seizures in individuals with multiple independent spike foci (Teskey et al., 1999), as often seen in patients with several brain tumors.

Pharmacoresistance and Conditioned Tolerance

Focal epilepsy is often refractory to treatment with anticonvulsant drugs. Although the pathophysiologic mechanisms underlying this resistance are unknown, Potschka and Löscher (2005) have identified a proportion of amygdaloid kindled Wistar rats as not responding to anticonvulsant drugs. These rats did not respond to phenytoin with an increase in ADT and were also shown to be resistant to many other major anticonvulsant drugs. A retrospective analysis of nonresponders revealed that plasma concentrations of phenytoin, kindling parameters, electrode location, and placement of electrodes are not responsible for the nonresponsiveness; instead it is related to genetically determined differences in the expression of the multidrug transporter P-glycoprotein. Nonresponding animals may thus prove to be useful in determining the acquired pharmacoresistance that comes with repeated seizures.

In terms of anticonvulsant tolerance, Post et al. (2005) have observed that although carbamazepine, diazepam, and valproate are initially highly effective in suppressing seizures kindled with suprathreshold stimulation, over a brief period of time the drugs lose effectiveness. Tolerance is not observed in animals that receive equivalent doses of the anticonvulsants after each seizure. The loss of anticonvulsant efficacy is thus an associative

phenomenon, termed contingent tolerance, and differs from conventional pharmacokinetic tolerance. After establishment of contingent tolerance to the anticonvulsant effects of drug, anticonvulsant effects can be restored by triggering a number of seizures without the drug or even triggering seizures with the drug given postictally. However, introducing a seizure-free or drug-free period does not reverse contingent tolerance. Thus kindling can again serve as a useful tool for investigating the acquisition of anticonvulsant tolerance in the clinical setting.

The Consequences of Multiple Seizures – Interictal Behavioral Dysfunction

It has been said the behavioral comorbidities with epilepsy are the rule rather than the exception. Cognitive and behavioral abnormalities occur with alarming frequencies in people with epilepsy, including deficits in verbal and visual memory that may not be directly linked to the occurrence of seizures. Furthermore, changes in fear and anxiety are some of the most common emotional disturbances associated with epilepsy of temporal lobe origin. It is often difficult to determine whether behavioral impairments are a result of seizures or other factors, such as medication. Furthermore, given the difficulties with the stigma associated with epilepsy, it is important to ensure that any causal relation between seizures and persistent aberrant behavior is real and unimagined. The fact that certain epileptic-related interictal behaviors can disappear after successful surgical treatment implies that there is a relation between the two. We and others have used kindling to study the relation between epileptogenesis and cognitive change and emotionality (Teskey and Corcoran, 2009).

Conclusion

Kindling involves a profound and permanent increase in the brain's susceptibility to seizures. It is associated with long-lasting changes in sensory, cognition, emotional, and motor behavior and, in some species, with the development of spontaneous seizures. We conclude that kindling is a valid model of clinical epilepsies.

Abstract

This article outlines the development of kinship studies in anthropology from their beginning to our days. It reviews classic debates on descent and marriage, the role of gender studies in rethinking kinship categories and the more recent contributions approaching the subject from the perspective of the body, aesthetics, and new reproductive technologies. In doing so, this article provides a critical approach to assess the fundamental and ongoing contribution of the kinship studies to the discipline of anthropology.

Studies in kinship, and the related institutions of marriage and the family, have until recently been central to anthropological investigation and debate. The problem of handling the topic of kinship cross-culturally is the key to understanding the historical development of a large majority of anthropology's central analytic concepts, theories, and methods. Deliberations over the puzzles of kinship and marriage gave rise to the discipline's most sophisticated technical and theoretical elaborations, and its most virulent, ever-present controversies. It was also assumed to be the area of technical competence, the most demanding of rigor in thought, through which anthropology could best defend its scientific respectability. As a result, kinship was that aspect of social life that became the linchpin for the unfolding of all the grand paradigms of thought within anthropology, whether it be Morgan's narrative of evolutionism (1871), Malinowski's functionalism (1930), Radcliffe-Brown's structural-functionalism (1952), or Lévi-Strauss' structuralism (1969). As Fox (1967) could still comment, "kinship is to anthropology what logic is to philosophy or the nude is to art; it is the basic discipline of the subject." The situation has, however, changed.

Nowadays at least two major questions can be asked. First, why did anthropologists predominantly prioritize kinship over politics, economics, and religion? Second, why lately have they shown a decided *lack of interest* in kinship, or rather in 'kinship' as it was conceived traditionally within anthropology? The answers will take us to problems in the major presuppositions underlying anthropology's highly valued analytic constructs of kinship and society. Although it has been the case that kinship from the start has always been the object of strident debate, it is only since the 1960s that the legitimacy of the topic itself began to be queried. In more recent years the process of doubting has accelerated due to very basic epistemic shifts within anthropology in the wake of feminism and other modes of disciplinary self-inspection about its claims to knowledge. One prevalent conclusion forthcoming from such transformations is that much of received kinship theory is no longer seen as justifiable.

The Narrative of Kinship

Law and Order by Another Name

The primary puzzle for the anthropologist throughout the first half of the twentieth century was how to explain the maintenance of order within the 'simple societies' of far-flung regions where anthropologists conducted their research. Such societies lacked the basic law and order organizing institutions of Western society. They had no government to speak of, no marketplace, as we know it, and no law courts, police, or armies. It was clear that they did not compartmentalize their social life into the distinct and separate institutions that we recognize as kinship, economics, politics, and religion. Anthropologists found instead that these peoples used the *idiom of kinship* to frame most of their activities, including those with political, economic, and religious intent. Analytically, the step from this insight was to view kinship to be the major institution of 'tribal' societies, and the kinship tie to be the one that compelled all others in social relations. Kinship, as the strongest of social bonds, became seen as the basis through which 'primitive' societies maintained order; it was through kinship ties that people created relations of social solidarity. Thus, 'social structure,' that is, those rules regulating the kinship, marriage, and residential institutions of a people that endow social role and identity, and which, therefore, perpetuate societal relationships, became anthropology's proper object of inquiry (e.g., see Radcliffe-Brown, 1965). Everything else, a society's morals, law, etiquette, religion, politics, and education, was to be studied as but an aspect of social structure (Radcliffe-Brown, 1965), or in other words its kinship system.

The emphasis anthropologists placed upon the problem of 'societal order' cannot be stressed too much. As Firth comments, the perception of order was fundamental to their investigation (Firth, 1961). An underlying concern was over what could replace the authority of government in 'simple' societies, and the answer was to view kinship as having this coercive power. In other words, it was the kinship system that came to be understood as playing the same official function among 'primitive' peoples as government does in western societies. The reasoning leading to such a conclusion is circular,

for kinship as a system became defined as the primary source for the rules and regulations that provided for order and continuity within 'native' society. It was presumed that the status, role, rights, duties, and obligations of a person in a 'simple society' were forthcoming from and ascribed by the person's place within the kinship system. The primary societal organization of these societies was then understood to be 'kinship based,' and it was the 'kinship polity' (see Fortes, 1969) forthcoming from either patrilineality or matrilineality that was the key concern. The slippage was simple: we have government, while they have the politics of kinship.

The Plot Thickens: The Distinction between the Domestic and the Jural

The 'law and order' thrust of traditional kinship studies, which equated the kinship system (of 'primitives') to 'society' itself, also came to include the critical distinction between the 'domestic' and 'jural' domains of kinship. The realm of the domestic was composed of relations of filiation between parents and children; it was the domain of the hearth, the family, the husband, his wife, and his children. In Fortes' terms (1969), it was the domain where the 'axiom of amity' reigned. In contrast, within the 'jural' domain the everyday relations of amity and filiation were for the most part irrelevant, for the principles of descent and lineage ruled its membership and provided the backbone for its jural structures of dominance and subordination. It was the jural domain that comprised the polity and, thus, provided society with its order and continuity. The prescriptions and regulations of the kinship polity (composed of its 'corporate descent groups') were what ruled and constrained 'primitive' people. A man's jural status, rights, and obligations within society were in essence provided by his place within the lineage of his birth. Genealogy determined one's political status, and one's rights to land and other entitlements.

Given the above narrative of the place of kinship in 'native' societies, we can understand that the received wisdom of kinship theory until as late as the 1970s was that unilineal descent systems were necessary as a sticking plaster of 'primitive' societal order – despite increasing evidence to the contrary. As Radcliffe-Brown (1965) asserts, "unilineal institutions in some form, are almost, if not entirely, a necessity in any ordered social system." Even Lévi-Strauss, in his major critique of descent theory in kinship studies, finds the existence of unilineal descent essential to the logic of his model of elementary structures of marriage exchange. He says that this is because the social cohesion of elementary systems of kinship that are premised on the notion of groups of men exchanging wives requires a rule of descent, for the groups themselves must be defined by such a 'stable' rule of descent (Lévi-Strauss, 1969). One should be aware, however, that Lévi-Strauss began his formidable attack upon the prevalent view of 'descent as societal order' in 1949, and that his stress upon alliance over descent as the salient ordering principle of 'primitive society' did not become part of mainstream debate until the 1960s (e.g., Leach, 1961; Needham, 1964), but also see the earlier debate between Radcliffe-Brown (1953) and Dumont (1953). The concern of Lévi-Strauss, it is to be noted, was with creating a minimal model of society by showing the ways in which kinship groups were integrated through rules of marriage exchange, that is, he wished to demonstrate how classifications of kinship and marriage logically provided a broader level of societal integration than that achieved through rules of descent alone.

The rather chauvinistic reductionism of the structural functionalist and structuralist grand paradigms of society and societal ordering, where society itself was to be equated with male structures of order and control, took another couple of generations to unveil and unravel.

The Question of Definitional Rigor

Kinship, Descent, and Marriage

In itself, a fuller ethnographic record began steadily to undermine many of the major analytic constructs of kinship and societal order, particularly the idea that 'primitive society' was universally based upon exogamous, corporate, land-holding, unilineal descent group structures. By the 1950s and 1960s reports of field research especially from the Pacific on kinship systems that were not premised on a unitary rule of unilineal descent but upon cognatic, bilineal, ambilineal, or double descent principles became legion (cf Bohannan and Middleton, 1968). The debate over the unitary view of unilineal descent basically was closed by the influential article by Scheffler (1966), who was able to demonstrate through the ethnography by then at hand that notions of descent were used among different peoples, and by the same people, toward highly varied ends, and not necessarily toward that of corporate group structure.

By the 1970s, for instance, through the ethnography from Amazonia that began to enter mainstream debates on kinship and marriage, it became clear that the notion of descent itself could hardly be declared a universal principle of 'primitive' social ordering, for there were peoples who did not recognize a principle of descent as relevant for any social or political purpose (e.g., see Rivière, 1969; Overing, 1975). Even kinship and marriage as analytical constructs per se came also under attack, especially the notion of achieving any type of unitary view of either (but also, see Leach's (1961) earlier hacheting of these sacred constructs of societal ordering). We find Needham (1971) announcing flamboyantly that "there is no such thing as kinship, and it follows that there can be no such thing as kinship theory!" He was referring to 'minimal' definitions of kinship when framed in the context of genealogically reckoned jural rights, such as their allocation and transmission from one generation to the next. Cross-culturally, the ethnographic evidence could not uphold a totalizing view that assumed a predictable relationship between the cultural constructs of kinship and its classification, social roles, rights, and obligations, and the allocation of individuals to particular types of social groups. It was this unitary package of kinship as part and parcel of particular politico-jural orders that earlier anthropology had indeed upheld.

Even more courageous for the times are Rivière's (1971) queries into the analytic concept of marriage. He argues against any jural definition of marriage, and suggests instead that the institution of marriage first be viewed structurally, as one of many relationships conceived possible between men

and women. It was his reading of the ethnographic literature that anthropologists had been defining institutions cross-culturally as 'marriage' when the said institutions in fact had "no feature in common other than that they are concerned with the conceptual roles of male and female" (Rivière, 1971). In other words, to understand what marriage is for any given people the question of the cultural construction of gender relationships must be understood, rather than the jural relations between groups of men that entail their exchange of women.

It is significant that Rivière's fieldwork experience had been with indigenous peoples of Amazonia, for whom anything approaching a 'jural' relationship usually would be stretching the point, as too would lineages and descent group ordering as normally discussed in the literature. It was as difficult to find corporate land-holding groups among Amazonian people, as the elders who might rule them. There were no *groups* of men forming ties of alliance through the exchange of their women. Instead, ties of marriage, which moreover were highly salient to Amazonian constructs of sociality, were linked to a principle of cognation and not descent. As a consequence the contributions of Amazonian specialists, in line with Dumont's (1957) reading of marriage alliance in India, played a major part in the later reinterpretation and unraveling of both alliance theory as first formulated by Lévi-Strauss and descent theory as formulated by Fortes and Radcliffe-Brown.

The Structural Analysis of Kinship Terminologies: The Power of the Paradigm

It is by now obvious that we cannot achieve an analytic definition of the construct of kinship and related institutions that would be both universally adequate and at the same time respectful of indigenous understandings and knowledge. In short, anthropology cannot, even if it wished, arrive at a universal definition of kinship. Part of the dilemma is of course linguistic, insofar as most of the important analytic terms of anthropology have not only been highly abstract but also continued to carry the complex historical baggage of western thought and practice. Terms, such as society, community, family, kinship, descent, lineage, or structure, function, and system, are to be used at the peril of totally eluding another people's understanding of what they are doing socially – which, one would think, is the very *raison d'etre* of the anthropological task. As anthropology slowly came to realize, any 'definitional rigor' to be achieved through the use of any of these terms is well-nigh impossible. Such constructs tend to sit within particular and forceful paradigms of social order, and therefore carry all the litter of such grand narratives. Structural-functionalism was followed by structuralism, and the structural analysis of kinship terminologies was a particularly obvious case of a paradigm so powerful that its highly reductive results killed for the time being the possibility of interesting further advances being made in kinship theory, the very area where anthropology was once so creative and rich in debate.

The overwhelming allure of structural analyses of kinship can be ascribed to the power of their methods, which wed anthropology to advances in modern linguistics, a field considered to have become the most scientific of the human sciences. The methods and models of formal analysis were so enlightening of previously misunderstood structures that they gave promise to a mathematical rigor and definitional clarity that would transform anthropology into a 'true science.' Their initial success was so stupendous (e.g., see Lounsbury, 1968) that they seemingly made child's play of previous attempts to provide order to the complicated structures of many 'native' kin terminologies. Anthropologists were taught to be more rigorous in discerning the logical differences between systems. Such sophistication in method was greatly needed in anthropology, and for its example we can be only grateful.

However, as Overing (1987) has noted, *the method* became confused with worldview. The logic of the method through sleight of hand became equated to the logic of terminological use, and thus also with indigenous thought itself. As a result, we arrived once more at the 'universal' to what Schneider so aptly derides as the anthropological 'Doctrine of the Genealogical Unity of Mankind!' (Schneider, 1984) or the genealogical meaning of kinship terms. Kinship is, everywhere, first and foremost about genealogical relatedness (see especially, Scheffler, 1978), a resoundingly uninteresting conclusion to come in the wake of such dazzling structuralist performances. It was also a judgment that was highly suspect. It appears that the method itself allowed for no other interpretation because the meanings of terms were made to fit not only the domain of logic, but also western commonsense notions about what kinship is. The demand itself of formal analysis for logical rigor reduces the number of its elements that account for meaning to very few: affinity as well as consanguinity can be allowed, but not the further complications of what such notions might possibly mean from the indigenous point of view. It was the niggling doubt over this issue (where are all the people?) that drove many anthropologists away from the technical chore of analyzing kinship logics. As Campbell (1985) remarks, the very abstract level at which structural analysis operates is about the tenth remove from anything going on in daily practice and thought.

In somewhat more recent formal analyses of kinship terminologies in the hands of scholars, such as Héritier (1981) we moved in the more promising direction of not assuming indigenous meaning. The aim instead is to specify the structural possibilities of a given classificatory system that in turn frame or limit the choices made in the world of reality. In short, the exercise is no longer directed toward the task of uncovering hidden layers of meaning, but to explore the interplay between structure and the semantics of actual use. This, indeed, was a road worth traveling.

Is There Hope for Kinship?

Schneider (1984) advises anthropologists not only to stop looking for 'kinship,' but also all the other meta-cultural categories of economics, politics, and religion which, together with kinship, form a quartet of societal domains. This was an idea embedded in European culture that has been willy-nilly incorporated into the European social scientist's analytic schemes. While we can heartily agree with Schneider's full blown rampage against the anthropological treatment of the topic of kinship, such concordance does not, however, entail total dismissal of the study of those social relationships, and

their classifications, that were once, more or less, subsumed under the label of 'kinship.' People do bear children, and there *is* a social framework through which they do so, and through which these children are raised to become adult members of human social groups. The members of these social groups follow particular practices in the course of which relationships that are highly significant for them are developed, as too are very interesting ways of thinking about them. With all this we can agree. The overriding question still remains – how do we understand and translate such practices, relationships, and ways of thinking?

Happily, since the 1980s, anthropologists have developed a myriad of ways to approach subjects that formerly would have been classified under the general rubric of 'kinship.' While nowadays the topic of something called 'kinship' does not loom large in the literature, such issues as 'self,' 'agency,' 'gender,' 'body,' 'intimacy,' and the life of values and affect, do. The topics of personhood, emotions, and aesthetics are much more likely to take their place in the titles of doctoral theses than those of kinship, affinity, and jural rules. Thus, we see that the 'technical' language of anthropology has been transformed in the wake of the shifts of attention away from something we once called the 'jural-political domain,' with its contrast to something we labeled 'the domestic group.' Attention is removed from the notions of social structure and prescriptive behavior, and those of rights and obligations. In their place, idioms of equality and inequality are now being explored, and such values as nurture, sharing, generosity – and those of peace and violence. The stress is upon ambiguity, process, the everyday, and a multiplicity of voices, rather than upon grand structures, rules and regulations. The emphasis tends to be upon context and the performative, and not hidden rules of practice and thought. Such shifts in direction have often been undertaken in a spirit of rebellion, by feminists, but also many others, against the ethnocentrisms underpinning the narratives of anthropology. The gain has been that anthropologists are presenting very different pictures, certainly in their richness, of the ways other people view, act, and experience the world. In short, it is rich ethnography, not grand theory, that drives our students and most of our colleagues today.

The Impact of Gender Studies

It has also made all the difference to the ethnographic endeavor to include the subject of women, and especially women's voices. In the process we have time and again discovered a rich symbolic world that demands an understanding of the interplay of men and women, and their respective knowledges, that makes travesty of the simplistic 'male only' models of yesteryear. It is only by understanding both male and female (often complementary or conflicting) perspectives that gender relations among another people can begin to be comprehended. As gender studies progressed, it became absolutely clear that the authoritative voice of the ethnographer was insufficient, as too that of the male 'informant.' Nor can we speak from the perspective of a generic female, for there is no such thing. There is ever a plurality of voices, a seemingly helter-skelter chiming that provides, significantly, fertile layers of evaluative contextualization, the recognition of which has in the end changed our anthropological visions of culture and society.

All those kinship structures through which men established important relationships with each other through the exchange of their muted women, which became the model of 'society'; all those 'political' roles and statuses through which men who controlled the political domain came to be the knowledge holders of their culture – these were the topics that once were recognized as primary anthropological concerns. From the 1970s onward, once women were inserted firmly within the context of 'establishment' discourse in anthropology, the consequence was a true 'Kuhnian' shift of paradigm.

One major contribution of the early writings on gender was to make anthropology clearly aware of its exclusion of women as a topic for study, and how such oversight was, moreover, linked to the male bias of dominant theoretical and methodological assumptions of the discipline, and beyond that to major strands of western thought in which anthropology played its part. In *Women, Culture & Society*, its authors show how women, like men, transculturally "are social actors whose goals and strategies are intrinsic to the process of social life" (Rosaldo and Lamphere, 1974), and that "even in situations of overt sex role asymmetry women have a good deal more power than conventional theorists have assumed" (Rosaldo and Lamphere, 1974). It became quickly obvious that major presuppositions and procedures of the discipline needed to be reconsidered radically in order to include the agency of women. In other words, studies of social life and its organization needed to include women as actors and speakers and not as mere passive, muted objects of men. It slowly came to be seen that women as well as men played a major role in the creation of social ties of community life.

There is by now a large amount of ethnography telling of indigenous peoples among whom the women, both ideologically and in practice, control their own labor, and the products of it, as shown in the recent literature on Amazonia. The ethnography of Lowland Central and South America has shown that activities of both men and women – different but complementary – reproduce sociality (Overing, 1986; McCallum, 2001; Belaunde, 2001). Gender is seen as a matter to be created, and formed, and not as a fixed attribute of bodies. The topic of corporeal substances is often found to be the key to understanding the gendering of bodies. In Amazonia, it is particularly blood and menstruation that play a crucial role, as Belaunde has demonstrated:

> Blood among indigenous Amazonian people brings together the biological, the intellectual and the spiritual, because the management of the flow of blood during the life cycle is a constitutive process, not only of fertility, but also of health, labor, creativity, well being, spirituality, personal identity and interethnic relations. To understand the difference between men and women from an Amazonian perspective necessarily entails a comprehension of the scope of corporeality, created through dietary and seclusion practices, and of predation and communication with cosmic beings, linked to the flow of blood.
>
> Belaunde, 2005: 18–19

Likewise, other substances, such as breast milk, contribute to the formation of gendered bodies. For example, among the Kuna, baby boys and girls are differently treated in relation to such maternal substance, which is not only conceived as

nurture, but also provides their bodies with gender features (Margiotti, 2010).

Values – and the structures of equality and inequality linked to them – may not be so straightforward, but ambiguous, as among the Hagen of New Guinea where there is constant play between egalitarian and hierarchical principles (e.g., Strathern, 1988). There are also now many ethnographic examples showing that the quality of the relations between the genders may well be subject to perspective, where females have a very different view from males of the strength of their respective roles and participation within the social life of the community (e.g., Keesing, 1987). This stress in studies of gender upon the critical importance of presenting perspective has led to energetic debate over the epistemological foundations of anthropology, which in turn has transformed the question, the topics, and the methodology of the discipline – and in the end its own self image as having the right of authorial privilege.

The Emergence of the Body and Aesthetics

The creation, gendering, and more generally, the treatment of bodies in different phases of the life cycle, has become an increasingly important topic in the study of indigenous socialities in the last 30 years and has provided crucial new insights into their kinship systems. By looking at how bodies are fabricated through daily processes of nurturing, conviviality, the observance of taboos, ritual seclusion and body decorations, Americanist anthropologists have been able to gain a better understanding of how Amerindians conceive themselves as living in groups of people related by substances. In brief, to recreate and maintain society it is essential to make human bodies that share the same qualities and affects. Often this process of creating kinship is understood to be in contraposition to opposing predatory forces, such as those of animals, that seek to incorporate human beings into their society by way of attaching their own, animal, affects onto the bodies of newborn humans (e.g., Londono Sulkin, 2000, 2012). Hence, understanding indigenous ideas of the social entails understanding their ideas and practices relating to bodies (Seeger et al., 1979). It is therefore of paramount importance to understand how, in each specific case, bodies become the focus of ritual practices and processes of feeding. In short, we are realizing the importance of understanding the specific ideas of the body that each society holds. The practices of bodily fabrication are usually aimed at imparting young people with the specific knowledge that teaches them to create 'bodies that know' (McCallum, 1996), that is, endowed with those moral human capacities that distinguish humans from other beings and that form the basis for the constitution of kinship. The process of fabricating the bodies of kinspeople entails the skillful management of multiple relationships with alterity. This is a topic that has interested a number of scholars in recent years, and which has been dealt with through an alternating focus on how relations are managed both inside the group of living human beings and outside in the wider space of neighboring groups, enemies, allies, and nonhuman beings (Overing, 1985b; Londoño Sulkin, 2000, 2012; Viveiros de Castro, 2001; Vilaça, 2002).

A further elaboration, in recent years, has been that of unraveling how decorations and ornamentations are key practices for the fabrication of bodies, which indeed endows them with those qualities that render them human and thus capable of regenerating kinship relations. This is a growing field of study that has the merit of showing how aesthetics is an extremely productive field to refine our understanding of indigenous forms sociality, and ideas of personhood and agency. Bodily decorations, such as body painting, tattoos, featherwork, beadwork, and clothing, are often ways of rendering visible the inner qualities of persons (Strathern, 1979), their capacity of fostering creative forms of sociality (Overing, 1989), and women's capacities to bear children (Gow, 1999). Indigenous notions of aesthetics are indissolubly linked to the creation of bodies, and therefore their study sheds light on how persons and social praxes are constituted (Fortis, 2010). Body painting and other forms of decoration are not only means of creating human bodies, they also make bodies resistant to predatory attacks from malevolent beings (Lagrou, 2007), or endow them with the capacities to act in social contexts inhabited by foreign others (Ewart, 2007). It has therefore become increasingly evident how ideas and practices originally considered, from a western perspective, as pertaining exclusively to the field of aesthetics, are in fact part of the whole fabric of everyday life, which includes, but is not limited to, those categories that were traditionally the object of kinship studies.

Reproductive Medicine

As Schneider (1984) argued, an axiom critical to kinship theory has been that the social and cultural attributes of kinship are derivative of the biological relations of reproduction. A reaction to Schneider's work has been a bourgeoning interest in the meanings of kinship in Euro-American contexts. Reproductive medicine and biotechnological advances have provided a fascinating context for the analysis of kinship meanings and practices aimed at forging new families (Strathern, 1992, 2005; Edwards, 2000; Carsten, 2000; Edwards and Salazar, 2009). Thus, one new 'anthropology of kinship' analyses Euro-American understandings of relatedness by putting on the map topics, such as adoption and foster care, surrogate motherhood, and gamete donation in national and international contexts (Ragoné, 1994, 2000; Howell, 2006). This further illuminates the link between kinship and new forms of commodification of bodies and reproductive material, as well as issues of race and inequality (Birenbaum-Carmeli and Inhorn, 2009). By the same token, these new kinship studies have signed a definitive rupture with old paradigms of nature and culture divide, rethinking ethnographically ideas of the natural and the artificial (Strathern, 1992). On a theoretical level, some of these studies confirm the importance of procreation in western ideas of kinship. Procreation is viewed as a transaction of genetic material. This material is 'passed down' across generations to form new relatives (Strathern, 1992, 2005). Idioms of genetics are therefore employed to refer to notions of origin and belonging, which are key to western ideas about kinship (Edwards and Strathern, 2000). Likewise, technological novelties in the field of reproduction and the new forms of families therefore emerging are interpreted through kinship ideas concerning the importance of

localities, naming, nurturance, and affects. Nurturing and bringing up children are equally constitutive to kinship, and remain key topics to understand changing ideas and practices in contemporary societies.

Kinship by Another Name? Networks of Relationships and Personal Kind Terms

We find that Schneider and Needham, as pioneers in the deconstructing of key concepts of kinship theory, were merely tapping the surface of a modernist creation for which the very notion of kinship was but one aspect of a multifractaled edifice filled with assumptions about society and the social order, that in turn were tied to networks of ideas about the relation of the family to other societal institutions, and the relationship between the sexes, the private and the public, the dominant and the subordinate, all of which were implicated further by presuppositions about the nature of human existence, and its progress, which in addition were premised upon ontological notions of the priority of reason over the emotions, and so it continued through an enormous number of other dualisms and bundles of relations pertinent to the western imagery of society and the world, and the elements of which they were comprised. Our notion of kinship carried with it the interarticulations of this entire structure.

The interesting lesson that has been learned more recently through changing the types of questions anthropologists' ask is that other people's views of the social relationships of everyday life are as enmeshed as our own within wider networks of meaning. They also include ontological presuppositions about the nature of human existence and capabilities for sociality that are linked to bundles of relationships and arrays of ideas about the world that are as complex as our own. How do we then understand these other sets of linkages, so unlike our own? That has become a primary question. The quest for understanding their interconnections has in part required the unpeeling of our presuppositions about reproductory and biological processes, parenting, the nature of the material world, and the interconnections of all of these things to what we call Society (cf Strathern, 1992).

Overing (1985a) has suggested that to understand better the complexity of indigenous social thought, we should change the label of what we have been calling 'kinship terms' to 'personal kind terms.' This involves a radical switch in perspective that concomitantly raises the conceptual status of these terms to one more closely aligned to the indigenous view and practice. As with many of our own constructs of 'natural kinds,' 'personal kind terms' are also highly abstract, philosophically important concepts that defy unitary definition (e.g., see Overing, 2006). They share the open-endedness and elusiveness that is typical of all abstract terms that comprise complex relational properties. The difference is that personal kind terms do not refer to the world of nature, which is the western domain of competence, but to qualities of personal relationships, the area that indigenous people have opted for theoretical elaboration (cf Horton, 1979). We have reduced their personal kind terms to our own very weak language of kinship, one that speaks of 'consanguinity,' 'affinity,' 'social category,' and 'amity,' which is often a bad mistake. These terms, as used in everyday life, can have metaphysical weight that goes well beyond our western notions of a 'biological' relationship or one through marriage. Moreover, the quality of the relationship they demonstrate, as, for instance, one of nurturing, teaching, treachery, competition, or predation, may override a more 'physical' kind of relating. Will this man or woman work tranquilly with me, or have predatory designs that will make me ill?

Certainly in Amazonian ethnography, the emphasis today in investigations of peoples' use of relationship terminologies is often upon the metaphysical and/or moral loading of the classifications (e.g., Teixeira-Pinto, 1997; Viveiros de Castro, 1992; Overing, 1985a). For instance, Kidd writes about the Enxet of Paraguay that:

> Their understanding of why they act as they do centres on their concept of the waxok, an aspect of the self that is both intensely private and inherently social. They insist that their social behaviour – both appropriate and inappropriate – can be explained by the physical – or metaphysical – state of the waxok. Furthermore, because the waxok is also the centre of cognition, people can also consciously transform it so as to enable themselves to act in either a self-centred or other-regarding manner. It is an explanation that, I believe, we should take seriously if we want to understand indigenous social life and it is one that finds its root in the practice of child-raising, in the creation of 'good/beautiful' people who have been taught not only how to think but how to feel. It is this waxok-centred combination of thinking and feeling that enables the Enxet to act appropriately and which, ultimately, guides them as they strive to generate sociality and engender tranquillity.
>
> Kidd, 1999

The peoples of Amazonia have been difficult for anthropologists to believe, and to an interesting extent still are (cf Overing, 1999). For many of these people the personal ties of parenting, nurturing, sharing, and pooling are not premised primarily on a notion of 'biological linkage' or a 'linkage through blood,' or membership within a jural group, but which instead are generated over time through consistent and processual action. As such, the personal quality of a relationship as made manifest through everyday practice is paramount to its classification. In other words, the ongoing quality of a relationship (as in the 'growing' of a child by a parent and child, the mutual care of brothers, or sisters, or of any other personal relation) may have generative value in a material sense that goes far beyond the minimal possibilities that are endowed through the act of sex (e.g., Gow, 1991). For sure, the personal kind terms that are here being applied to their nearest and dearest, and to those further a field, are about reproductory possibilities, but it is not 'reproduction' in the sense that the anthropologist imagined it in traditional kinship theory.

Kinship Is Alive and Well!

In fact, we can say that kinship studies are as alive and well as always in anthropology, in that the personal relationships and activities of parenting, nurturing, and the processes of generating and gendering of bodies into social adulthood hold center attention. Such studies are, however, unrecognizable as pertaining to the kinship theory of yesteryear. A similar

reorientation of concentration is as clear in Melanesian studies as in those of Amazonia (e.g., Strathern, 1988) where personal relationships are discussed through categories very different from the former ones of prescriptive rule, roles and statuses, and social structure, and where the talk instead, as among Amazonianists, is upon the indigenous understandings of such matters as gender distinctions, the contents of the self and the mastery of them, and the construction of human bodies; it is about indigenous ambiguities over the nature of personhood and the various possibilities of agency in this world and others, and the elaborate relation of these issues to indigenous practice, the life of affect, and their metaphysics. In other words, a dialogue is being created between us, the anthropologists, and them, the peoples of New Guinea or Amazonia, over what it means to be human in this world, or female humans, male humans, or betwixt and between? What does it mean to be social beings in this world? How do we go about attaining this state? If for other people the western grand distinctions between society and nature do not hold, what other possibilities of an interesting kind are there? These are very different questions from those asked in mainstream anthropology in the 1970s and 1980s.

Abstract

This article introduces core concepts and theories in the evolution of kinship and reviews empirical research that applies these perspectives to understand individual physiology, behavior, and social structure. After presenting theoretical definitions and methods used to measure genetic relatedness, the article reviews the mechanisms individuals use to recognize one another as kin. Research on inclusive fitness and kin selection demonstrates how relatedness between individuals affects individual actions and social interactions. This work establishes connections between the evolution of kinship and research on multilevel selection and major transitions in the evolution of complexity. A brief review suggests how the unique features of human kinship can illustrate the interactions between evolution, culture, and multiple pathways of inheritance.

Introduction

Kinship is a fundamental component of evolutionary theory. In the natural sciences, the term is used to define relationships between individuals who are genetically related (*see* Kin Selection). Two individuals who are kin possess similar genetic material due to a shared common ancestor. Therefore, kinship emerges from one of the evolution's fundamental conditions: the process of transmitting and inheriting genetic material from one generation to the next. Because modes of reproduction can vary from one species to the next, precise measures of genetic relatedness between individuals must derive from the particular processes of genetic replication and transmission for each species. Yet, because all species reproduce, species-specific measures of genetic relatedness, their effects on the physiology and behavior of individuals, and the social structures arising from interactions among kin can be compared across species to investigate general evolutionary patterns and principles. In the broadest sense, all living organisms are kin because all share a common ancestor, although the precise connections among contemporary and extinct species are often far in the past and only partially known. Thus, kinship can be understood as a continuum, extending from investigations of an organism's physiology and behavior in the present and near past to the deepest evolutionary histories of all life forms. The fact that core principles of kinship can be extended across the entire range of this continuum illustrates the importance of kinship in evolutionary theory.

This article introduces core concepts and theories in the evolution of kinship and briefly reviews the diverse empirical research that applies these perspectives to understand individual physiology, behavior, and social structure. The first section focuses on the essence of kinship relatedness, explaining how this term is calculated and the variations that arise from different modes of reproduction across species. The second section examines how relatedness between individuals affects social interactions by reviewing research on inclusive fitness and kin selection. The third section describes mechanisms of kin recognition, which are fundamental to linking calculations of relatedness to individual actions and social interactions. The fourth section presents research on common social structures that emerge from kin selection, including reproduction, parental investment, cooperative breeding, and group formation. The fifth section shifts toward the broader end of the kinship continuum to establish connections between the evolution of kinship and deeper evolutionary histories, including research on multilevel selection, genomic imprinting, and major transitions in the evolution of complexity. Finally, the article concludes with human kinship, suggesting how the various ways our species defines relatedness can illustrate the interactions between evolution, culture, and multiple pathways of inheritance.

Relatedness

Relatedness between two individuals is the essence of kinship. Evolutionary scientists define relatedness in genetic currencies, because the process of genetic replication and transmission across generations is a fundamental component of evolution. Although Darwin understood that the act of reproduction transmitted traits from one generation to the next, he and his contemporaries famously lacked accurate, detailed knowledge of these processes (*see* Evolution, History of). Gregor Mendel's research on genetic inheritance and hybridization was published several years after Darwin's *On the Origin of Species*, but its importance was not understood until research on genetics began to coalesce in the early years of the twentieth century. Even then, it was not until several decades later – through the research of Ronald A. Fisher, Sewall Wright, J.B.S Haldane, and others – that the theory of evolution by natural selection was integrated with population genetics to establish the 'modern synthesis' between heredity and evolution. A key development leading up to the modern synthesis was Wright's coefficient of relationship, which defined the relatedness between two individuals as the sum of correlation coefficients calculated for every genealogical path connecting them to a common ancestor. In most cases, this correlation coefficient equals the probability that two individuals share a gene via descent from a common ancestor, above the random expectation that individuals share a gene due to membership in a population or species. This probability is now most often known as the coefficient of relatedness, or simply r.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.81041-7

The coefficient of relatedness can range in value from one – between identical twins, clones, or one's relatedness to self – to values negligibly greater than zero – between individuals whose closest common ancestor lies many generations in the past. How one calculates r depends on the species' mode of reproduction. For example, in a species that reproduces asexually by budding offspring from a parent, the coefficient of relatedness between parents and offspring – and among siblings – will equal one. In this case, because all of the offspring's genes are received from the parent, there is 100% probability that a gene found in one will appear in the other (setting aside variation introduced by mutation). However, in a diploid species that reproduces sexually – like our own – each offspring inherits half of his or her genes from each parent. In this case, a simple way to calculate the coefficient of relatedness is to (1) define the genealogical pathways that connect two individuals, (2) value each link in the path according to the probability of inheriting a gene, (3) multiply the probabilities for each link on a path connecting two individuals, and (4) sum the product of probabilities for each path. For example, two full siblings are connected by a genealogical path via the father ($0.5 \times 0.5 = 0.25$) plus a path via the mother ($0.5 \times 0.5 = 0.25$). When we add the product of probabilities along each path ($0.25 + 0.25$), we obtain a coefficient of relatedness equal to 0.5. This method for calculating coefficients of relatedness works for all sexually reproducing diploid species, but must be altered to produce correct results for species with different modes of reproduction.

In practice, there are multiple ways one can measure coefficients of relatedness. First, one can collect genealogical information for all individuals in a population, and then use this information to apply the simple method described above, known as the 'pedigree method' (Queller, 2010). This method is accurate as long as one obtains genealogical information for each individual with sufficient generational depth. Unfortunately, in many cases it is difficult to obtain genealogies that go beyond a few generations, limiting the practical usefulness of the pedigree method in some contexts. Fortunately, advances in genetic sequencing have enabled additional techniques based on variable neutral genetic markers (Weir et al., 2006). For example, short tandem repeats of DNA (microsatellites) or single-nucleotide polymorphisms (SNPs) can be compared between two individuals to ascertain their coefficient of relatedness with high accuracy. Although this method can be useful when genealogical information is absent or difficult to obtain, specialized equipment and skills for genetic sequencing are necessary, posing difficulties for researchers who lack the ability to implement these techniques.

Kin Selection and Inclusive Fitness

Measuring genetic relatedness between individuals is important because this information can be used to understand the evolution of social interactions. An individual's actions not only affect his or her own reproductive success, they may also affect the reproductive success of others who interact with that individual. William D. Hamilton developed the concept of inclusive fitness to capture the significance of genetic relatedness for the evolution of these social interactions (Hamilton, 1964) (*see* Kin Selection; Sociobiology: Overview). Whereas an individual's direct fitness is determined by his or her success in producing offspring, an individual's inclusive fitness combines an individual's reproductive success (direct fitness) with the effects that individual's actions have on the reproductive success of related individuals (indirect fitness). The core insight of inclusive fitness is that a trait that appears to decrease an individual's direct fitness may actually increase that individual's inclusive fitness, resolving apparent contradictions between the evolutionary process of natural selection and the persistence of physical traits, behaviors, and social structures that impose net costs on an individual's direct fitness.

Hamilton applied the concept of inclusive fitness to predict the evolution of such costly characteristics with a simple inequality: $c < b \times r$. This inequality states that a physical trait, behavior, or social structure that imposes net costs on an individual's direct fitness (c) can evolve via natural selection if those costs are less than the benefits of that characteristic for other individuals (b), multiplied by the coefficient of relatedness between them (r). Because the coefficient of relatedness varies between 0 and 1, it effectively devalues the indirect benefits of the costly characteristic as genetic relatedness declines between two individuals. For example, a costly characteristic that reduces an individual's direct fitness by 1 unit but increases the reproductive success of a full sibling ($r = 0.5$) by 3 units can evolve via natural selection because the indirect benefit for the individual ($3 \times 0.5 = 1.5$) exceeds the direct cost of the physical trait, behavior, or social structure. However, that same costly characteristic would be unlikely to evolve as a result of interactions between half siblings ($r = 0.25$) because the indirect benefits ($3 \times 0.25 = 0.75$) do not exceed the direct costs ($c = 1$) for the individual. Although a complete explanation for the evolution of a specific costly trait in a particular species at a given moment in time would involve more complex models from population genetics and evolutionary game theory, the simple inequality above – often known as Hamilton's rule – provides a useful starting point for investigating the relationship between evolution and kinship that can be applied across a wide range of species and contexts.

Understandably, researchers applying Hamilton's rule tend to focus on variation in coefficients of relatedness. However, it is important not to lose sight of the fact that other elements of the inequality – costs for direct fitness and benefits for indirect fitness – can play an equally important role. Although coefficients of relatedness are often equal for a variety of social relationships, factors that determine direct and indirect fitness can vary significantly across these relationships, particularly in species with multistage life histories. For example, in a diploid, sexually reproducing species like ours, coefficients of relatedness between parents and offspring ($r = 0.5$) equal coefficients of relatedness between full siblings ($r = 0.5$). Yet full siblings are almost always closer in age and the periods each depends on his or her parents for support often overlap, creating the potential for conflicts of interest that are more intense than those between parents and offspring. In this example, the greater age differences between parents and offspring can effectively reduce the direct costs of a particular trait, behavior, or social structure for the parent and increase the indirect benefit via aid to the offspring. Direct costs may be lower for parents because older

individuals often possess greater resources, benefit only marginally from small increases in resources relative to offspring, and hold fewer remaining opportunities to reproduce. In contrast, offspring often possess limited resources, benefit greatly from small increases in resources due to key life history trade-offs at early stages of development, and hold many opportunities to reproduce once reaching adulthood, all of which can significantly increase the indirect benefits of a costly trait held by parents. These asymmetries in age, resources, sensitivity to trade-offs, and reproductive potential are less pronounced among full siblings, meaning that a similar costly trait held by one sibling may be less likely to evolve due to the indirect benefits of providing aid to another sibling who may be competing for parental resources. Variations in coefficients of relatedness will always be important for investigating kinship and the evolution of social interactions, but the example above illustrates why it is important for researchers to also explore factors that affect the other terms of Hamilton's inequality – the costs and benefits of direct and indirect fitness for physical traits, behaviors, and social structures.

Kin Recognition

With sufficient genealogical or genetic data, it is not too difficult for researchers to calculate coefficients of relatedness and investigate how kinship affects social interactions. For the kin who are the focus of this research, however, the information necessary for calculating coefficients of relatedness is often quite limited, raising an important question: How do individuals recognize one another as kin? Because coefficients of relatedness are unobservable, species have developed various kin recognition mechanisms that exploit contextual cues, physical traits, social structures, and other circumstances that correlate reliably with genetic relatedness. On a general level, a kin recognition mechanism includes four essential components (Penn and Frommen, 2010). First, a kin recognition mechanism requires a phenotypic or contextual cue that is sufficiently variable among individuals, is correlated with genetic differences, and either remains stable across an individual's life span or is at least present during a critical phase when the recognition mechanism operates. Second, a mechanism requires a process of recognition, where an individual perceives a cue and compares it to some template that defines how that cue corresponds to a degree of relatedness. Third, the results of the recognition process are used to apply decision rules that specify how an individual will act according to relatedness. Fourth, these decision rules are assessed and used as the basis of actions that are biased in some way by the relatedness between the two individuals. These four components can take many different forms, but kin recognition mechanisms can be classified based on the kinds of cues they utilize: (1) contextual cues based on spatial proximity and familiarity from past interactions and (2) phenotypic matching via visual, auditory, and olfactory cues.

Contextual Mechanisms

Although coefficients of relatedness are not perceptually salient, individuals can often exploit consistent social structures and environmental patterns to recognize kin. These contextual mechanisms of kin recognition can include spatial proximity due to nests or other persistent residential groups as well as familiarity developed through repeated interactions. A mother who gives birth to offspring can be confident she is related to those offspring, and to the extent those offspring are raised together and interact repeatedly, they can assume they are related to one another. Fathers, however, are often in a more precarious position to make such assumptions, depending on the mating strategies prevalent in the social group (Widdig, 2007). Even in species with a high prevalence of monogamy, extra-pair mating can occur, reducing the effectiveness of spatial proximity as a mechanism of kin recognition for fathers. This variation in the effectiveness of contextual mechanisms opens possibilities for diverging strategies among individuals within a species. One parent may benefit from circumstances that cause another to overestimate relatedness, while the other would benefit from a more accurate assessment, creating dynamic interactions, as in the case of cuckoldry and other forms of sexual conflict involving paternity certainty and kin recognition (Arnqvist and Rowe, 2005).

Interestingly, contextual mechanisms of kin recognition often provide opportunities for conflict and exploitation between members of different species, as in the case of brood parasitism. Cuckoo species (family Cuculidae) provide an iconic example, laying their own eggs in the nests of other birds and leaving them to be raised by the unsuspecting parents of the other species. Brood parasitism is often successful due to the victim's reliance on contextual mechanisms of kin recognition such as the presence of eggs in one's own nest. Many species have evolved counter-strategies to discriminate their offspring from parasite offspring, in turn resulting in more elaborate attempts at deception by the species practicing brood parasitism (Feeney et al., 2012). Research on incest avoidance and familiarity provides another iconic example of contextual mechanisms of kin recognition, this time with a confluence rather than a conflict of interests among individuals. Building on the ideas of Edvard Westermarck, scholars have examined contexts where individuals raised together display reduced levels of attraction and mating success compared to those raised apart, even when individuals raised together are genetically unrelated. Coresidence is hypothesized as a mechanism allowing individuals to recognize closely related kin (e.g., siblings) and avoid the deleterious effects of mating with them.

Phenotypic Matching

Just as members of one species resemble each other more than members of another species, it is possible that more closely related individuals will resemble one another to a greater extent than distantly related individuals. If differences in genetic relatedness are correlated with salient phenotypic characteristics, individuals may be able to recognize kin by assessing phenotypes of other individuals. Penn and Frommen distinguish between three kinds of phenotypic matching: familiarity dependent, familiarity independent, and self-referential (2010: pp. 12–15). Familiarity dependent matching occurs when an individual assesses the phenotype of another individual at one time, and then compares this assessment with perceptions of

that same individual's phenotype at a later time. Put simply, individuals learn what phenotypic traits are associated with kin, and then use these traits to identify those kin as they encounter them again across the life span. Thus, familiarity-dependent mechanisms of kin recognition rely on contextual mechanisms discussed earlier – such as spatial proximity – to identify phenotypic traits of kin. These phenotypic traits are then used to identify kin in absence of the original contextual mechanisms, as when siblings disperse from a natal nest.

Phenotypic matching can also be extended to unfamiliar individuals. By comparing the phenotypic traits of unfamiliar individuals with phenotypic traits of familiar kin, an individual can extend contextual mechanisms beyond their spatial and temporal restrictions. For example, a contextual mechanism for recognizing siblings that relies on the spatial proximity of a nest and temporal proximity of a litter could lead siblings to become familiar with one another, and then recognize one another by sight, sound, or smell after dispersing from the nest (familiarity-dependent matching). If these visual, auditory, or olfactory cues are somewhat consistent across litters reared by the same parents, then these cues could also be used by individuals to recognize older or younger siblings from separate litters. Because these litters did not share the same nest, neither contextual nor familiarity-dependent mechanisms would allow them to recognize one another as siblings. Failure to recognize siblings from different litters could have significant negative consequences for inclusive fitness, as in the case of inbreeding depression. Individuals who are able to develop familiarity-dependent phenotypic cues of relatedness and apply these cues to unfamiliar individuals (familiarity-independent matching) can avoid mating with close relatives and escape the deleterious effects of inbreeding.

While potentially effective in a variety of circumstances, these two kinds of phenotypic matching depend on contextual mechanisms to develop templates that associate particular traits with kin. A third kind of phenotypic matching does not depend on any contextual or familiarity mechanisms; it simply depends on an individual's ability to compare its own phenotype to the phenotypes of unfamiliar individuals. Such self-referential phenotypic matching mechanisms are limited to those visual, auditory, and olfactory traits that an individual can perceive in itself and identify in others. Self-referential mechanisms may be particularly effective when context and familiarity do not allow individuals to accurately assess relatedness, such as when individuals are reared alone, in litters where genetic relatedness varies due to paternity uncertainty, or in litters that include unrelated individuals from the same or another species (Hauber and Sherman, 2001).

Although these recognition mechanisms may not always capture precise coefficients of relatedness, it is clear that individuals in many species are successful at using kin recognition mechanisms to guide social interactions and act in ways that increase their inclusive fitness. Evidence of effective kin recognition can be found in a variety of taxa, including humans (Kaminski et al., 2009; Park et al., 2008), nonhuman primates (Silk, 2002; Rendall, 2004), mammals (Griffin and West, 2003; Mateo, 2003), birds (Nakagawa and Waas, 2004; Zelano and Edwards, 2002), fish (Ward and Hart, 2003; Griffiths, 2003), invertebrates (Gherardi et al., 2012), and microbes (Strassmann et al., 2011). In some species, multiple mechanisms may be used in tandem. In other species, mechanisms may operate at specific development stages instead of across the life span. Understanding these processes of kin recognition and investigating their evolution is an important line of inquiry for further research.

Kinship and Social Structure

To the extent individuals are able to recognize kin, natural selection should favor physiological traits, behavioral strategies, and social structures that utilize this information to maximize inclusive fitness within the particular constraints of the individual's environment. Hamilton's research is considered a fundamental breakthrough in our understanding of the evolution of sociality because it provides a clear concept (inclusive fitness) and a simple rule ($c < b \times r$) that allows us to investigate adaptations that emerge from interactions among individuals with varying degrees of genetic relatedness (Hamilton, 1997). A comprehensive review of the literature building on Hamilton's work is beyond the scope of this article (Gardner et al., 2011; Queller, 2011). Instead, it will suffice to highlight some broad domains of social structure that are shaped by the evolution of kinship, starting with the foundations of mating and parental care and extending to more elaborate social structures involving cooperation, group defense, and fission–fusion dynamics.

Considering the fundamental role of the transmission and inheritance of genetic information in evolution, it should not be surprising that kinship is important for our understanding of reproduction. Genetic relatedness between individuals shapes reproductive strategies at all stages, from choosing potential mates to producing and caring for offspring (Pizzari and Gardner, 2012). In sexually reproducing species, mating with close kin (incest) can have significant, negative effects on offspring survival and reproductive success (inbreeding depression), limiting the inclusive fitness of close kin who mate with one another. There is evidence that mechanisms of kin recognition help related individuals avoid incest in a variety of species (Pusey and Wolf, 1996), including birds (Nakagawa and Waas, 2004), humans (DeBruine, 2005; Rantala and Marcinkowska, 2011), mammals (Mateo, 2002), and insects (Tabadkani et al., 2012). One of the most extensively investigated examples concerns the role of major histocompatibility complex (MHC) genes in regulating mating preferences (Bernatchez and Landry, 2003; Penn and Potts, 1999; Tregenza and Wedell, 2000). MHC molecules vary among individual members of a species, and this diversity plays an important role in immune function, helping to distinguish an individual's own cells from pathogens and other foreign cells. Genes that code for MHC molecules are transmitted from parents to offspring, and the molecules can be perceived by smell, providing an opportunity for kin recognition via phenotypic matching mechanisms. In addition to the value of avoiding incest, the benefits of MHC diversity for immune function can lead individuals to seek mating partners with dissimilar MHC molecules. There is evidence that MHC genes play a role in partner choice in humans (Havlicek and Roberts, 2009; Wedekind, 2007), primates (Knapp et al., 2006; Setchell and

Huchard, 2010), birds (Zelano and Edwards, 2002), fish (Eizaguirre and Lenz, 2010; Reusch et al., 2001), and reptiles (Miller et al., 2009; Olsson et al., 2005).

Parents of all species invest energy, time, and material resources to produce offspring, and the patterns of parental investment that emerge can be explained by measuring coefficients of relatedness, investigating mechanisms of kin recognition, and documenting physiological and behavioral traits that are biased by these mechanisms. Genetic relatedness plays a key role in evolutionary theories of parental investment, helping researchers navigate the potential conflicts and confluences of interest among individuals with varying degrees of kinship. The interactions of strategies among kin in the context of reproduction and parental care are complex even when focusing on parents and offspring. These complexities grow significantly when more distantly related kin become involved. Research on cooperative breeding and alloparental care illustrates the importance of kinship for understanding the evolution of social structures involved in reproduction and parental investment. Cooperative breeding occurs when individuals sacrifice some of their own reproductive effort in order to contribute to the reproductive effort of other individuals as alloparents (Komdeur et al., 2008). Alloparents are often – but not always – genetically related to the parents they assist, and evidence suggests that alloparents can recover the direct fitness costs of these strategies through a combination of indirect fitness benefits and enhanced mating opportunities, diminished predation risk, and other benefits of group membership (Bergmüller et al., 2007; Clutton-Brock, 2002; Lukas and Clutton-Brock, 2012).

While the indirect fitness benefits of cooperative breeding strategies are an intriguing example of the influence of kinship on social structure, other benefits of group membership found in a wider range of species are also shaped by genetic relatedness. Some of the earliest investigations of kinship and social behavior focused on the production of alarm calls in social birds and rodents. Individuals are vulnerable to predation while foraging outside their burrows or nests, and alarm calls are used to alert group members to the presence of a predator. Because the alarm also attracts the attention of the predator, an individual who sounds the alarm may be exposed to a higher risk of predation than an individual who spots a predator and silently seeks safety. Evidence from a variety of studies suggests that associations between genetic relatedness and alarm calls – mediated by factors such as age, sex, dominance rank, and migration rates – underlie the evolution of this antipredation strategy (Blumstein and Armitage, 1997; Hollén and Radford, 2009), although other factors that affect risks to alarm callers can also be important (Shelley and Blumstein, 2004).

Evidence suggests that kinship can also drive the formation and dissolution of social groups. Fission–fusion dynamics (i.e., the dynamic process of merging and splitting between and among subgroups within a population) reflect demographic growth and the availability of resources, and kinship often – but not always – plays an important role in identifying which neighboring groups will combine or which subgroups will cleave apart (Aureli et al., 2008). African savannah elephants live in social groups that vary frequently in spatial location and composition, and genetic relatedness among older females predicts patterns of fission and fusion (Archie et al., 2006). Similar results arise from research on fission–fusion dynamics in giraffes (Carter et al., 2013), bats (Popa-Lisseanu et al., 2008), rhesus macaques (Widdig et al., 2006), and dolphins (Frère et al., 2010). Even when the boundaries and composition of groups remain more or less stable over time, individuals often disperse from one group to the next according to factors such as age, sex, and dominance rank (Ronce, 2007). These patterns of dispersal have consequences for the relationship between kinship and social structure, particularly the balance between cooperation and competition among kin and non-kin (Lawson Handley and Perrin, 2007; Hatchwell, 2010; Lehmann and Rousset, 2010).

Although kinship shapes processes and patterns of reproduction, parental investment, cooperative breeding, defense, and group formation in many species, there are some species that integrate these domains of social life to a much greater extent, embedding individual actions within elaborate social structures shaped by the evolution of kinship. Eusocial species – defined as those that exhibit a reproductive division of labor, cooperative breeding, and overlapping generations within the social group (Wilson, 1971) – are perhaps the most striking examples of kinship's influence on the evolution of physiology, behavior, and social structure. Many eusocial species combine sterile worker castes with reproductive 'queens' that monopolize mating opportunities and benefit from extensive alloparental care, cooperative resource production, and territorial defense provided by other members of the social group. In these cases, some individuals sacrifice their own opportunities to reproduce and devote their energy to increasing the reproduction of a single related female, deriving inclusive fitness benefits entirely from indirect reproduction. Indeed, Hamilton's original formulation of inclusive fitness and kin selection theory was intended in part to explain the evolution of eusociality in a number of insect species (ants, bees, wasps), which Darwin singled out as a troublesome, potential contradiction to his theory of evolution by natural selection. Since Hamilton, scholars have continued to refine definitions of eusociality (Crespi, 2005; Lacey and Sherman, 2005), nominate additions to the list of eusocial species – including mole rats (Burda et al., 2000), beetles (Biedermann and Taborsky, 2011), shrimp (Duffy and Macdonald, 2010), and humans (Wilson, 2012) – and debate the role of kin selection, group selection, and other evolutionary mechanisms underlying the evolution of eusociality (Gardner and Ross, 2013; Hughes et al., 2008; Wilson and Hölldobler, 2005).

Kinship, Multilevel Selection, and Major Transitions

Hamilton's research on inclusive fitness and kin selection was among the first to demonstrate the advantages of exploring conflicts and confluences of interest across varying levels of biological and social hierarchy. Whereas evolutionary theories of cooperation and conflict had primarily focused on calculating costs and benefits at the level of individual organisms and groups of organisms, Hamilton's approach utilized what has come to be called 'the gene's-eye' perspective (Dawkins, 1976). This approach entails calculating costs and benefits of a trait from the perspective of a gene that codes for the

trait rather than the interests of the individual who carries the gene, opening up the potential for cooperation and conflict to occur at multiple levels simultaneously, including within individuals. This approach revolutionized the study of social interactions because physiology, behaviors, or social structures that entail an apparent cost for an individual can nonetheless evolve due to benefits accruing to the putative gene underlying the trait. Prior to the work of Hamilton, George C. Williams, Robert Trivers, and others, it was common to explain traits that were costly for an individual in terms of their benefits to the individual's social group or species (Williams, 1966; Trivers, 2002). Although the surge in research adopting the gene's-eye perspective tipped scholarly consensus on the evolution of cooperation and competition toward explanations that emphasized the interests of genes and individuals at the expense of groups, these debates have been rekindled by a number of researchers who emphasize the importance of natural selection operating at the group level (Sober and Wilson, 1998; Nowak et al., 2010), provoking in turn a strong response from proponents of Hamilton's approach (Abbot et al., 2011; Bourke, 2011b).

One important, positive outcome of this debate has been a renewed interest in multilevel selection (Okasha, 2006) and theories that articulate how evolutionary dynamics operate simultaneously across multiple levels of biological and social hierarchy. Although scholars continue to disagree about the relative importance of natural selection operating at the levels of genes, individuals, and groups in empirical contexts, there is widespread agreement that evolution can, in principle, operate at multiple levels. This consensus emerges in large part from the work of John Maynard Smith and Eörs Szathmáry on 'major transitions' in evolution (Maynard Smith and Szathmáry, 1997). A major transition occurs when previously independent units (genes, cells, individuals) combine to form groups, lose the ability to reproduce independently of those groups, and become interdependent units whose evolutionary fate depends in large part on their ability to function cohesively. Although such transitions have clearly occurred in the past – including transitions from prokaryotes to eukaryotes, protists to multicellular organisms, asexual reproduction to sexual reproduction, and solitary to eusocial species – evolutionary scholars still struggle to understand the specific conditions, dynamics, and thresholds that bring about major transitions (Calcott and Sterelny, 2011). The conceptual and methodological tools developed to understand the evolution of kinship – including coefficients of relatedness, kin recognition mechanisms, and inclusive fitness – have a key role to play in this effort because they help scholars link conflicts and confluences of interest at different levels of hierarchy to modes of reproduction and forces of selection operating across these levels, from genes to individuals to groups (Birch, 2012; Bourke, 2011a).

Whereas research on multilevel selection and major transitions extends inquiry outward, beyond the tangible lines dividing individuals to investigate less perceptible boundaries of social groups, others continue to pursue the implications of the gene's eye perspective for understanding equally imperceptible dynamics within individuals. Research on genomic imprinting and kinship is a particularly intriguing example. Genomic imprinting refers to instances when a gene is expressed (or not) depending on whether it is inherited from a mother or a father (Pomiankowski, 2002). David Haig proposes an explanation for patterns in genomic imprinting that derives inspiration from Hamilton's work, suggesting potential conflicts of interest between maternal and paternal genes can be used to predict the presence of imprinted genes and their effects on physiology and behavior (Haig, 2004). For example, genes regulating parental investment might be expected to demand greater resources from the mother when inherited from the father than when inherited from the mother, due to the difference in costs and benefits of maternal investment from the perspective of each parent. The best documented example concerns a gene encoding for insulin-like growth factor 2 (IGF2) in mammals, which is only expressed when inherited from the father and compels the offspring to demand greater resources from the mother in-utero (Reik et al., 2003). IGF2 and other examples of genomic imprinting illustrate ongoing cooperation and conflict at the genetic level, alluding to deeper evolutionary histories of conflicting interests that were mitigated, but not entirely resolved, by major transitions (Burt and Trivers, 2008).

Kinship and Culture

This review of research on the evolution of kinship has focused on describing key concepts, methods, and theories at a general level in order to illustrate the potential for complementary research across species. However, in order to support consilience across the divide between the natural and social sciences (Wilson, 1998), it is important to consider insights from the long tradition of research on human kinship, which is often unfamiliar to evolutionary scholars in the natural sciences. Although biological dimensions of human kinship have long been acknowledged and investigated by social scientists, cross-cultural variations in the way people define and recognize kin – as well as implications for social structures – have been the primary focus of research (Parkin and Stone, 2004). A complete review of the cultural and biological dimensions of human kinship is beyond the scope of this article (see Cronk and Gerkey, 2007; Kurland and Gaulin, 2005). Here it will suffice to briefly reframe research on human kinship in relation to the conceptual structure for the evolution of kinship offered above, moving from kinship terminologies to some common social structures that emerge from the interaction of biological and cultural definitions of relatedness. In this task, brevity is accomplished by focusing on insights from the growing body of research by social scientists (particularly anthropologists) who integrate evolutionary and cultural perspectives (Shenk and Mattison, 2011).

While evolutionary scholars define relatedness in genetic currencies, social scientists define relatedness by following the cultural categories utilized by the people with whom they work. Cultural definitions of relatedness vary dramatically from one place to the next, evident in different kin terminologies that lump and split social relationships into categories that often depart from those defined by biological coefficients of relatedness. Although this variation is impressive, it is important to acknowledge that the observed variation in kin

terms does not exhaust the full range of logical possibilities for lumping and splitting kin (Kemp and Regier, 2012). In other words, cross-cultural variations in kin terminologies exhibit patterns, and these patterns may provide clues to understanding why people's cultural definitions of relatedness differ from relatedness defined in genetic currencies. Kin terminologies often split or lump kin according to a limited number of factors, including gender (male or female), laterality (paternal or maternal), generation (older or younger), and genealogical distance (close or distant) (Jones, 2010; Jordan, 2011).

Although kin terminologies establish cultural calculations of relatedness that certainly differ from biological calculations of relatedness, this disconnect is often quickly – and perhaps mistakenly – assumed to mean that concepts and hypotheses derived from evolutionary theory are irrelevant for understanding human kinship. However, it is interesting to note that the same factors people use to split or lump categories of kin often direct our attention to consistent variations among individuals and social structures that may have consequences for inclusive fitness. In other words, kin terminologies may convey information about the fitness consequences of interacting with kin – culturally defined – by combining coefficients of genetic relatedness with factors crucial to calculating the costs and benefits of interactions with different individuals. Recall that evolutionary scientists studying inclusive fitness and kin selection in other species have warned against focusing exclusively on variation in coefficients of relatedness and ignoring factors that affect costs to direct fitness and benefits to inclusive fitness, which are both important parts of Hamilton's inequality. Similarly, it may be unwise for scholars studying human kinship to use disconnects between cultural and biological definitions of relatedness as a reason to ignore evolutionary theory's relevance. Instead, the wide variety and consistent patterns in human kin terminologies may provide a guide for developing and testing hypotheses about the relationship between cultural and biological definitions of relatedness and exploring the importance of inclusive fitness in human social structures.

Evolutionary anthropologists have begun to investigate the intersections of cultural and biological definitions of relatedness in a variety of social domains where human kinship is important. Some have used inclusive fitness and kin selection to investigate the evolution of marriage practices, including monogamy (Fortunato and Archetti, 2010), polygyny (Borgerhoff Mulder et al., 2006), and polyandry (Starkweather and Hames, 2012) (*see* Marriage Systems, Evolution of). Others have synthesized research on nonhuman primate social dynamics with anthropological research on kinship to understand the role of exogamy – marrying outside one's kin group – in extending cooperation to and restricting competition among wider social circles (Chapais, 2008). Similar approaches have been used to understand human mating, marriage, and child care as cooperative breeding strategies that have parallels in nonhuman primates and other mammals (Hrdy, 2011).

Unilineal descent systems – where membership in a group is traced along paternal or maternal lineages – provide another common pattern in human kinship that can be understood by applying concepts and tools from evolutionary theory. Researchers have found that higher levels of extra-pair mating and paternity uncertainty are associated with matrilineal descent systems, perhaps reflecting the fact that calculations of genetic relatedness are more accurate across generations when traced via maternal lines due to diminished paternity certainty among men (Hartung, 1985). Similarly, others have found that the emergence of matrilineal or patrilineal descent in a particular place may be tied to the differential influence of inherited property – whether land, livestock, or status – on reproductive success of daughters and sons. When inheritance favors the reproductive success of sons, patrilineal descent is common, and when inheritance favors daughters, matrilineal descent is common (Fortunato, 2012; Mattison, 2011). A shift in the kind of property inherited can even lead to a shift in descent, as when African Bantu-speaking matrilineal horticulturalists became patrilineal pastoralists (Holden and Mace, 2003). Such instances of change in social structures tied to kinship often reveal underlying dynamics that can be understood using evolutionary theory (Leonetti and Nath, 2009).

While pursuing evolutionary research on human kinship, it is important to distinguish culture from behavior. Whereas behaviors are actions that can be directly observed and documented, culture is best defined as socially learned and transmitted information and ideas (Durham, 1992). For example, kin terminologies are socially learned and transmitted ideas about how to recognize kin that are distinct from behavioral interactions among kin, which may of course be informed by kin terminologies but may also be influenced by evolved predispositions. This distinction between culture and behavior is not intended to hold culture and evolution as opposed analytically. Rather, it is intended to define behavior as the domain for explanation, and culture and evolution as two potential pathways through which the information that informs behavior can be transmitted from one generation to the next (Cronk, 1999). For example, one of the primary functions of kin terminologies throughout the world is to define who is and is not allowed to marry and produce children. These prohibitions against incest may operate in tandem with evolved kin recognition mechanisms that help individuals avoid the biological costs of inbreeding. However, these prohibitions often depart from those defined by biological costs, applying asymmetrically – to kin on either the paternal or maternal side of the family, when both are equally related genetically – or extending to distantly related kin who pose little danger for costs of inbreeding. Rather than functioning simply to avoid inbreeding, kin terminologies often structure marital relationships that maintain or transform the boundaries between social groups. The practices of marrying within one's kin group – endogamy – or outside one's kin group – exogamy – often function to negotiate social structures, ascribe rights and obligations within groups, and form alliances between groups. Indeed, cultural marriage practices shaped by these aspects of social structure may even come into conflict with evolved kin recognition mechanisms aimed at avoiding inbreeding. A classic example concerns a Taiwanese 'sim-pua' marriage practice that betrothed children at an early age and transferred future brides to reside in the households of their future husbands. Despite the cultural prescriptions of these practices, researchers have found that partners in these marriages experienced less marital

harmony and produced fewer children than partners who were raised in separate households (Lieberman, 2009; Kushnick and Fessler, 2011; Wolf and Durham, 2004). In this case, evolved kin recognition mechanisms constrain the variation of cultural kinship practices, evident when we document associations between particular behaviors (incidences of marital strife, offspring produced), cultural practices (sim-pua marriages), and conditions that trigger evolved propensities (coresidence during early childhood).

This approach to studying human kinship can be used to explore interactions between culture and evolution as part of the growing research on gene-culture coevolution (Richerson and Boyd, 2004) (*see* Human Cooperation, Evolution of). Although many aspects of human kinship are unlikely to have close parallels in other species – such as kin terminology and unilineal descent – these exceptions can be valuable for understanding fundamental social dynamics that apply more broadly. For example, eusociality and cooperative breeding are found in relatively few species, but their unique features allow us to test predictions about inclusive fitness and multilevel selection that should, in principle, explain the conditions that lead to the presence or absence of both novel and common social structures. Although many important questions along these lines remain unanswered, this review of the evolution of kinship has highlighted some key concepts, theories, and empirical studies that provide a solid foundation for future work.

Abstract

Kinship involves social interactions and forms of social organization based on systems of culturally constructed social relations expressed linguistically through the kin terms constituting a kinship terminology. The organization and structure for these social relations expressed in a kinship terminology is formally modeled here as being part of an axiomatic theory in which a few, primary kinship concepts are the equivalent of axioms in a mathematical theory. The cultural knowledge embedded in a kinship terminology therefore is part of a cultural theory – analogous to a mathematical theory – that expresses the culturally salient kinship properties derived from the primary kinship concepts.

Introduction: The Domain of Kinship

Kinship involves social interactions and forms of social organization based on systems of culturally constructed social relations expressed linguistically through the kin terms constituting a kinship terminology. Formal modeling of structural patterning in the social relations expressed through kin terms began with Lewis Henry Morgan's systematic study of kinship terminologies in the mid-1800s. Since then, the analysis of kinship systems has been central to anthropological theorizing, though some aspects such as what constitutes the cultural criteria by which one person is the kin of another person are still topics of considerable disagreement. Regardless, all societies have a corpus of terms – a kinship terminology – that expresses for culture bearers their cultural concepts regarding kinship. A kin term referentially designates, in a culturally meaningful and mutually understood manner, the kin relation one person may have to another person, thereby identifying those who are kin to speaker and to each other.

The British anthropologist Rodney Needham usefully divided the domain of kinship into three aspects: (1) behavior – what people actually do, (2) rules – what people say are the rules or jural restrictions on behavior, and (3) categories and relations among categories. These divisions have content varying from less to more abstract and the third is the focus here for the formal modeling of kinship systems.

Modeling of categories and relations among categories has generally considered one of two related analytical frameworks: (1) the structure and organization of a kinship terminology or (2) the implication of prescriptive marriage rules for the structural integration of social units such as families, lineages, clans, or even whole societies. The first framework will be the focus of this article. For this framework, it has generally been assumed – though incorrectly – that kin terms are primarily linguistic labels for categories of genealogical relations. While kin terms have this function, it is secondary to the categories being derived from the implications of the primary kinship concepts embedded in a kinship terminology.

The organization and structure of the kinship relations expressed through a kinship terminology will be formally modeled by considering a few, primary kinship concepts to be the equivalent of axioms in a mathematical theory. The cultural knowledge embedded in a kinship system therefore incorporates a cultural theory – analogous to a mathematical theory – that expresses the culturally salient kinship properties derived from these primary kinship concepts. These concepts have roots both in (without being determined solely by or limited to) the biological facts of reproduction and in culturally defined marriage systems that define conditions for offspring to be fully recognized as social members of a society or a social stratum. Marriage rules – the cultural stipulation of the social facts sufficient for assigning a complete social identity to the offspring of a woman – structure the interconnections among social groups either positively through prescriptive marriage rules or negatively through incest taboos.

Primary Kinship Concepts

We begin by identifying culturally salient concepts of relatedness that are the axioms for cultural theories of kinship relations. These concepts derive from the universally recognized statuses of *motherhood*, *fatherhood*, and *spousehood*, each having different, culturally specific criteria for its implementation. In its default mode, motherhood involves 'mothering' – the positive caring, nurturing, and feeding behaviors that a female directs toward those she recognizes as her offspring – but 'mothering,' hence motherhood, is not limited to behaviors directed in this manner and can arise in conjunction with other practices such as adoption, suckling, and/or coresidence, among others.

Similarly, what constitutes fatherhood is culture-specific and the status can, but need not always, be initiated through cultural recognition of, and the meaning assigned to, a male's biological role in a woman becoming pregnant. In some societies, the biological role of semen in pregnancy is not given importance in local theories of reproduction and pregnancy is culturally attributed to other actions a man engages in that relate to establishing the social identity of a newborn.

Motherhood (fatherhood) leads to the concept of a *mother relation* (*father relation*) through associating mothering behavior with the dyad of two interacting individuals that is the locus for the behavior associated with motherhood. Cognizing a mother relation in this sense is not just a human capacity but occurs among the macaques (Dasser, 1988). The father relation in human societies, however, does not have a counterpart among

nonhuman primates since the status of fatherhood does not exist for most nonhuman primate species.

We can define the idea of a mother relation (father relation) through the ensemble of behaviors, B_{Mo}, associated with motherhood (B_{Fa}, associated with fatherhood). We define a *mother relation*, M, as follows.

Definition of Mother Relation M: For female person *s* and person *t*, let *s*M*t* (read '*s* is the mother of *t*') be true when *t* is recognized as the target for *s* when engaging in the mothering behaviors in B_{Mo}; that is, *s* takes on the motherhood status vis-a-vis *t* (see left side of **Figure 1** in gray) by virtue of engaging in the behaviors making up B_{Mo} with *t*, the recipient of those behaviors.

A *father relation*, F, may be defined in a similar manner using the behaviors in B_{Fa}.

There are several boundary conditions included in the cultural instantiation of these two relations: (1) if *s*M*t* or *s*F*t* is true, then $s \neq t$, (2) for no persons *s*, *t* is it the case that *s*M*t* and *s*F*t* are simultaneously true, and (3) for each person, *u* there is presumed to be a person *s* and a person *t* such that *s*M*u* and *t*F*u*. Another condition, corresponding to the assertion that a single female has the primary responsibility for the care and well-being of a child (Schneider, 1961), is that for persons *s*, *t*, and *u*, *s*M*t* and *u*M*t* are simultaneously true only when $u = s$.

Since both of these statuses require that there be a person who is the recipient of the behaviors, it follows that there is a reciprocal *daughter relation* and *son relation* for the mother and father relations definable from the perspective of the recipient of the B_{Mo} and B_{Fa} behaviors. The daughter relation can be defined as follows.

Definition of Daughter Relation D: For persons *s* and *t*, let *s*D*t* (read '*s* is the daughter of *t*') be true when *s* is female and either *t*M*s* or *t*F*s* is true.

A *son relation* may be defined in a similar manner.

The M and F relations are conceptually independent since *s* can be recognized as the mother of *t* without a person being recognized as father of *t*, or vice versa. However, cultural kinship systems are bilateral, meaning that the mother relation and the father relation are both axiomatic for generating kinship concepts. By itself, this would lead to conceptually disconnected sets of kinship relations. Matrilateral relations (those who are related to speaker through a sequence of one or more relations beginning with the mother relation and then followed by a parental or sibling relation when there is more than one relation in the sequence) and patrilateral relations (defined similarly except beginning with the father relation) would lack a conceptual connection.

The cultural institution of marriage conceptually forms a connection between the mother relation and the father relation, thereby removing disconnectedness. Through marriage, a spousehood status (see top part of **Figure 1**) is defined using culture-specific behavioral criteria that determine a symmetric *spouse relation* in a manner analogous to how the mother relation is determined from the motherhood status. Associating the social identity of offspring with

Figure 1 Motherhood and fatherhood are statuses determined by behaviors directed to another person (dashed arrows). Spousehood is a status determined by a marriage act (dashed arrow). Each is the basis for identifying when a relation holds between two persons. The three relations form a mediation structure (El Guindi, Fadwa, Read, Dwight, 1979. Mathematics in structural theory. Current Anthropology 20, 761–790; Read, Dwight, 2010a. Mathematical representation of cultural constructs. In: Kronenfeld, D., Bernardo, G., De Munck, V.C., Fischer, M.D. (Eds.), A Companion to Cognitive Anthropology. Wiley-Blackwell Publishing, Malden, MD) for the three categories (shown by boxes) labeled *mother*, *father*, and *child* with the indicated gender attributes. The structural opposition between the *mother* category and the *father* category is expressed through the *spouse* relation and each of the categories in opposition is linked to a mediating category (bottom box) through the *mother* and *father* relations, respectively. Persons *s*, *t*, and *u* may be categorized as indicated by the dotted arrows, thereby conceptually making *s mother of u* and *t father of u* and, reciprocally, *u* is *child of* s and *u* is *child of t*. The *child* category (lower box) has both male and female attributes as required for a mediating category. The spouse categorization conceptually makes *s spouse of t* and *t spouse of s*. Generally the biological sex of the person being categorized agrees with the gender of the category, though in some societies such as the *LoDagaba* of Ghana, Africa, a male person – a mother's brother – is categorized as a kind of mother and correspondingly is referred to by the term *madeb* whose literal meaning is 'male mother' (Goody, Jack, 1959. The mother's brother and the sister's son in West Africa. The Journal of the Royal Anthropological Institute of Great Britain and Ireland 89, 61–86). In several African societies such as the *Nandi* of Kenya, female fatherhood arises through female husbands (Oboler, Regine S., 1980. Is the female husband a man? Woman/woman marriage among the Nandi of Kenya. Ethnology 19, 69–88). Note: Terms, symbols, and arrows in gray refer to phenomena in the material domain and those in black refer to concepts in the cultural domain.

marriage ensures that there is at least a presumed, if not actual, spouse relation between a person who culturally instantiates the mother relation, if any, and a person who culturally instantiates the father relation, if any, for an offspring to have a complete social identity.

The mother, father, and child categories and the spouse, mother, and father relations are conceptually integrated through a *mediation structure* (El Guindi and Read, 1979; Read, 2010a). A mediation structure consists of an open, mediating category having a pair of attributes with opposite values that is linked to a pair of closed categories, each of which has associated with it one of the pair of opposite-valued attributes associated with the mediating category (see central part of **Figure 1** in black). The child category has the pair of opposite attributes, *male*, *female*, and is open since it categorizes the outcome of a biological birth. The mother category has the attribute *female*, the father category has the attribute *male*, and each is linked to the child category through the mother relation and the father relation, respectively. They are closed as there are culture-specific criteria for being culturally recognized as a mother or a father. The mother and father categories are, then, categories in opposition and conceptually one goes from the mother category to the child category using the mother relation and then from the child category to the father category using the inverse of the father relation, and vice versa. This link is culturally enabled through the institution of marriage and the associated spouse relation defined by *mother of child of father* is *spouse* is *father of child of mother*.

More succinctly, the spouse relation expresses the opposition between the mother and father categories by the computations, *spouse of mother is father* and *spouse of father is mother*. These computations map the female gender of mother to the male gender of father. The derived kinship system based on mother, father, and spouse will be bilateral. Also, it follows that a person can be categorized as father without reference to the biological facts of reproduction, as occurs in groups such as the Tiwi of Australia where *father* is the man currently married to *mother* regardless of his biological relationship to her child. Yet another implication is that the axiomatic foundation of kinship can neither be reduced to biological nor to cultural properties alone, as it necessarily incorporates both.

Family Structure

Kinship systems universally recognize a *sibling relation* derived from the biological fact that multiple offspring can be produced through reproduction. While each offspring may be categorized as *child* in the mediating structure shown in **Figure 1**, *siblinghood status* arises through behaviors between offspring framed by having at least one person in common categorized as mother or father. A sibling relation may be defined as follows.

Definition of Sibling Relation SB: For persons s and t, let sSBt (read 's is the sibling of t') be true when there is a u and a v such that both of uMs and uMt and both of vFs and vFt are true. The sibling relation expands the mediating structure (**Figure 2(a)**) into what we will call a *family structure* (see **Figure 2(b)**). It should be noted that this structure neither defines nor determines the empirical form of actual families. Rather, it illustrates the structural relationships among the axiomatic kinship relations that are integral to the concept of family.

Next we begin the construction of a *kinship domain* by first constructing a Family Space derived from the family structure. Then we add a Genealogical Space (GS) and a Kin Term Space and finally we indicate the structural relationships among these spaces.

Family Space

Kin terms identify a kinship relation between speaker and target person, whereas the primary kinship relations introduced above are from the perspective of an observer noting the behavior between the two members of a dyad. Shifting from an observer to an actor or agent perspective corresponds to introducing the universal concept of self into the family structure and changing, for example, the relation, 's is mother of t,' into, 's is my mother,' with t categorized as self. Introducing *self* transforms the Family Structure of relations into a Family Space of positions and their connections to *self*.

Two Family Spaces are possible, depending on whether the sibling relation is derived from the parent and child relations (see **Figure 3(a)**), or is primary (see **Figure 3(b)**). Both concepts regarding sibling relations are empirically found in

Figure 2 (a) The mediating structure from **Figure 1**. (b) Modified mediating structure with a sibling relation. The structure incorporates all of the elements for the concept of a family. The structure is that of a nuclear family, but actual families have empirical form depending on the cultural instantiation of the categories in the family structure.

Figure 3 (a) and (b) Solid arrows (black or gray) are the primary relations. Spouse is in a third dimension and connected to *self* by the spouse relation (double headed arrow). *Daughter* of *spouse* is *daughter* and *son* of *spouse* is *son* (dashed arrows). The mother and father positions are connected with the spouse relation (dotted, double-headed arrow). (a) Family Space based on constructing the sibling relations through parent: *sister* is *child* of *parent* and *brother* is *son* of *parent* (dashed arrows). (b) Family Space when the sibling relation is a primary relation (double-headed arrows).

human societies (see Marshall, 1983 for ethnographic examples of axiomatic sibling relations).

Genealogical Space

The GS consists of *genealogical paths* constructed from the relations in the Family Space through (1) each relation in the Family Space is a genealogical path and (2) if P and Q are genealogical paths, then the product PQ defined through concatenation is a genealogical path. GS consists of all possible products of the form $P = P_1, P_2, \ldots P_n$, $1 \leq n < \infty$, where each P_i, $1 \leq i \leq n$, is a relation in the Family Space.

For persons s and t, a *genealogical claim* connecting s to t consists of a list of persons, beginning with s and ending with t, such that all adjoining persons in the list satisfy one of the relations in the Family Space. A genealogical path, P, may (potentially) be instantiated recursively over a group G of persons as a genealogical claim from person s to some person t in G as follows. Instantiate *self* with s and find s_1 in G (if any) such that $s\, P_1\, s_1$ is true. If $n = 1$, set $t = s_1$ and the list, $[s, t]$, is the desired genealogical claim. Otherwise, recursively instantiate *self* with s_1 and find s_2 in G (if any) such that $s_1\, P_2\, s_2$ is true. If $n = 2$, set $t = s_2$ and $[s, s_1, t]$ is the desired genealogical claim. Otherwise, continue recursively in this manner. If there is a person s_i in G with $s_{i-1}\, P_i\, s_i$ true for all i, $1 \leq i \leq n$, then the genealogical path P determines the genealogical claim $[s, s_1, s_2, \ldots, s_{n-1}, t]$ connecting s and $t = s_n$. Conversely, each genealogical claim corresponds to a genealogical path.

Kin Term Space and Kin Term Maps

The size of the GS scales with k^n, where k is the number of relations used to form genealogical paths and n is the length of a genealogical path, hence GS is cognitively complex even for short genealogical paths. In all societies, this complexity is reduced to categories of genealogical paths corresponding to the 15–30 kin terms in a kinship terminology. Unlike folk taxonomies, though, kin relations can be computed directly by culture bearers from other kin terms using the knowledge they have of their kinship terminology as a system of interconnected terms. As reported in numerous ethnographic accounts, the calculations have the form of a *kin term product* (see Figure 4) defined as follows.

Definition of a Kin Term Product: If person s (properly) refers to person t using the kin term L and person t (properly) refers to person u using the kin term K, then the kin term M, if any, that

Figure 4 Definition of the kin term product, K o L = M, for the kin term L used by person s to refer to person t and the kin term K used by person t to refer to person u. The product is illustrated by the kin terms in parentheses. The English kin term *grandfather* is determined by the product of the kin term *father* with the kin term *parent* = (*mother*, *father*).

person *s* uses to (properly) refer to person *u* is the product of the kin terms K and L: M = K o L.

The kin term product makes it possible to generate the kin terms in a kinship terminology starting with the kinship relations in the Family Space. The lexeme K is a (*primary*) *kin term* corresponding to the Family Space relation R when there is cultural agreement that person *s* may (properly) refer to person *t* by K when *t*R*s* is true. For example, English speakers agree that it is proper for *s* to refer to *t* as 'my parent' when either '*t* is my mother' (*t*M*s*) or '*t* is my father' (*t*F*s*) is true for *s*, so *parent* becomes a primary kin term for English speakers. A new kin term may be constructed from a primary kin term K and an already identified kin term L by letting the kin term product K o L determine the relation person *s* has to person *u* when *s* refers to person *t* by the term L and *t* refers to *u* by the term K (see **Figure 4**). Naming this kin term product incorporates it as a kin term in the kinship terminology. The same name may be used for more than one product as part of the kinship concepts embedded in the kinship terminology. For English speakers, for example, *grandfather* is the name for the kin term product *father* o *mother* and it is also the name for the kin term product *father* o *father* (see **Figure 4**).

We visually display the structure of a kinship terminology with a *kin term map* (see **Figure 5**) made by letting each kin term be a node and drawing an arrow corresponding to a primary kin term (with a different arrow form for each primary kin term) from a kin term K to the kin term L when L is the product of the primary term with the kin term K. The kin term maps for the American/English kinship terminology and the terminology of the Shipibo Indians, a horticultural group in the eastern part of Peru, are shown in **Figure 5**. Structural differences in their respective kinship terminologies are immediately apparent. The Shipibo terminology has symmetry between matrilateral and patrilateral kin reflected in the symmetry of the women's designs used to decorate pottery, clothing, faces, and other parts of the body that relate to therapeutic aspects of curing and bewitching shamanistic practices (Roe, 2004). The American terminology has a contrast between lineal and collateral kin reflected in the practice of a woman and her children taking on the name of her husband even though lineal descent groups are not culturally recognized.

Generating a Kinship Terminology

The procedure for generating new kin terms through the kin term product suggests that kinship terminologies may share, despite their structural differences (see **Figure 5**), a common scheme for the generation of a kinship terminology as an abstract algebra consisting of the ordered triplet, <T, o, S>, where T is the set of kin terms including self, o is the kin term product interpreted as a binary operation over T with self an identity element (0 is included in T to ensure that o is closed over T), and S is a set of ethnographically validated structural equations giving the algebra its particular structure as displayed in the kin term map. Analysis of a wide variety of kinship terminologies leads to the following construction schema expressed as a sequence of steps (see Leaf and Read (2012) for a more detailed presentation; examples of generating a terminology can be found in Read (1984) (American terminology), (2010b) (Dravidian terminology), (2012) (Kung San terminology), Read and Behrens (1990) (English, Shipibo, and Trobriand terminologies), Bennardo and Read (2007) (Tongan terminology); and Leaf and Read (2012) (Kariera and Punjabi terminologies)).

Step 1: Generate an ascending structure of kin terms based on either the generating set (1) A = {self, P}, where P is an ascending primary term or (2) A = {self, P, G}, where G is a primary sibling term, along with the structural equations G o G = G ('sibling of sibling is sibling') and P o G = P ('parent of sibling is parent') included in S. Inclusion of a primary sibling term accounts for the defining structural properties of the terminologies that Morgan distinguished

Figure 5 (a) Kin term map of the American/English kinship terminology based on *parent*, *child*, and *spouse* as the primary terms. (b) Kin term map of the Shipibo Indians of eastern Peru based in *ea* ('self'), *papa* ('father'), *tita* ('mother'), and *bake* ('child') as the primary kin terms. Affinal kin terms have not been included.

as *classificatory terminologies*. For some terminologies, either the structural equation $A^n = 0$ or $A^n = A^{n-1}$, $n > 2$, that limits producing new kin terms in an ascending direction is included in S, where $A^n = A \circ A \circ \ldots \circ A$ (n times).

Step 2: Generate an isomorphic, descending structure of kin terms based on either the generating set (1) D = {self, C}, where C is a descending primary term or (2) D = {self, C, G*}, where G* is a primary sibling term distinct from G. (The sibling terms G and G* have interpretation as *ascending sibling* and *descending sibling*, respectively, though they are usually referred to as older sibling and younger sibling.) Include in S, the isomorphic version of any structural equation included in Step 1.

Step 3: Form a single structure with generating set G = A ∪ D. Include in S, the structural equation P o C = self ('parent of child is self' for consanguineal relations) that defines P and C to be reciprocal kin terms. If G, G* are in G, then include the structural equations G o G* = self = G* o G ('ascending sibling of descending sibling is self is descending sibling of ascending sibling') that define G and G* to be reciprocal kin terms.

Step 4: Introduce 'sex marking' of kin terms either by (1) adding sex marking elements m and f to S that are right-identities in S or (2) making an isomorphic copy of the structure generated in Step 3, but with a new term, self*, replacing self in the isomorphic copy. The structure and its isomorphic copy are interpreted as male-marked and female-marked terms, respectively. These two structures are joined to form a single structure of both male-marked and female-marked kin terms. Different ways the structures may be joined correspond to major structural differences among the classificatory terminologies.

Step 5: Introduce affinal terms by either (1) adding a spouse primary term, Sp, to S, along with appropriate structural equation such as Sp o P = P, Sp o Sp = Sp, and so on or (2) defining a kin term in S to also be an affinal term through a marriage rule, such as the prescriptive marriage rule in many Australian societies specifying that a man marries one of the women he refers to by such-and-such a kin term (e.g., the kin term for a cross-cousin).

Step 6: Introduce terminology specific kin term rules that locally modify the structure determined from Steps 1–5.

Step 7: Introduce any relevant culture-specific kin term distinctions that arise from usage of the terminology, such as the term with translation, 'younger brother of mother,' in the Tongan terminology due to inheritance rules.

The terminologies generated in this manner using the primary concepts of a kinship terminology have been found to have structure isomorphic to the structure shown in a kin term map for that terminology, hence the schema presented here can be considered to determine a theory explanatory of the properties of kinship terminologies.

Relations among the Family Space, the GS, and the Kin Term Space

The relations among the Family Space, the GS, and the Kin Term Space are shown in Figure 6 and derived as follows. Both the GS and the Kin Term Space are constructed from the relations in the Family Space, hence there is a natural mapping, h, of the GS into the Kin Term Space defined as follows. Map each path of length 1 to its corresponding primary kin term; for example, for the English terminology, h: M → *mother*. For all other paths, map the relations in the genealogical path to the kin term product of the corresponding primary kin terms and reduce this product to a kin term in the Kin Term Space. Thus for the genealogical path [M, B, D], h:[M, B, D] → *daughter* o *brother* o *mother* = *daughter* o *uncle* = *cousin*. (Note: products of kin terms are written from right to left to allow a product such as *mother* o *father* to be read as the kin term product 'mother of father,' whereas a genealogical path is written from left to right to allow a list such as [F, M] to be read as the claim, 'ego's father's mother.')

The mapping is a *homomorphism* since for genealogical paths $P = [P_1, \ldots, P_n]$ and $Q = [Q_1, \ldots, Q_m]$, $h{:}PQ = h{:}[P_1, \ldots, P_n, Q_1, \ldots, Q_m] = h{:}Q_m \circ \ldots \circ h{:}Q_1 \circ h{:}P_n \circ \ldots \circ h{:}P_1 = h{:}[Q_1, \ldots, Q_m] \circ h{:}[P_1, \ldots, P_n] = h{:}Q \circ h{:}P$. It is a *surjective* (onto) mapping since any kin term, K, in the Kin Term Space may be written as a product of primary kin terms, hence the genealogical path determined by a sequence of relations constructed with each relation in the sequence mapped by h to the corresponding primary term in the product definition of K will be mapped to K by h.

Predicted genealogical definitions of kin terms are given by the inverse mapping, h^{-1}, and the predictions match empirical observations. The mapping, h, it should be noted, ensures that computations with kin terms will be consistent with genealogical computations.

Formal Representation of Computations over the GS

Most symbolic systems devised for representing genealogical paths are essentially notation systems. One of the more elaborated symbolic representations of this kind is the Grafik symbol system (Atkins, 1974), but it does not represent a computational system for doing computations with genealogical relations. The latter has been developed formally by distinguishing between genealogical claims that conceptually link one person to another through a chain of persons connected by parent and/or child relations and an abstract positional schema for expressing the genealogical path embedded in a genealogical claim (Lehman and Witz, 1974). Culture bearers do not just make genealogical claims; they also do genealogical computations with the genealogical relations that provide the connections among the adjacent persons in a genealogical claim. Lehman and Witz define an abstract *Primary Genealogical Space* (PGS) as the multiplicative semigroup generated from four filiation symbols P^m, P^f, ${}^mQ$, ${}^fQ$ that represent the relations 'has male parent,' 'has female parent,' 'is child of male person,' and 'is child of female person,' respectively, and are derived from the upward lineation symbol P and its inverse downward lineation symbol Q, all subject to the structural equations $(P^x)({}^yQ) = 0 = ({}^xQ)(P^x)$, where x, y = m (male) or f (female) and $x \neq y$ (1974: p. 119). (Their PGS is essentially what is being called GS here.) The first equation says that a male (female) parent cannot also be a female (male) person having a child and the second eliminates genealogical

Figure 6 Relationships among the Family Space, the Genealogical Space (GS), and Kin Term Spaces. The GS may be mapped homomorphically onto a Kin Term Space, implying that the structure of the GS is carried over to a Kin Term Space. Genealogical definitions are determined by the inverse of the homomorphism mapping from GS onto Kin Term Space.

claim loops that go from a person to a child and back to the starting person. They show that from PGS a positional schema can be defined that formally represents the process of genealogical reckoning.

Summary

The kinship domain has been formally represented here as being composed of a Family Space of positions defined with respect to self, a GS of genealogical paths defined as sequences of relations from the Family Space, and a Kin Term Space defined through kin term products of the primary kin terms determined from the positions and relations in the Family Space and subject to equations that structurally express kinship concepts structuring a particular kinship terminology. The formal representation establishes that the GS can be mapped homomorphically onto a Kin Term Space, meaning that calculations made with genealogical paths will be consistent with computations in a Kin Term Space.

The formal representation relates to empirical observations through the systematic elicitation of kin terms from culture bearers (Leaf, 2006) conducted by asking about kin term products of the primary kin terms with the primary kin terms and then products with any elicited kin terms. The elicitation establishes that a terminology is conceptually bounded since any sequence of kin term products with a primary kin term eventually terminates, either because the next product does not yield a new kin term or it yields a previously elicited term (or possibly a variant on a previously elicited term such as great … great grandparent in English).

The homomorphism from the GS onto a Kin Term Space and the algebraic structure of the Kin Term Space together imply that the terminology provides a symbolic way, through the kin term product, to compute kinship relations in a manner consistent with genealogical reckoning. Thus the relationship between calculating with genealogical paths and the symbolic kin term computations with the kin term product is analogous to the relationship between calculating with counting numbers (where a counting number represents the cardinality of a set of objects) and symbolic number computations using the addition operation with the natural numbers. In both situations, a formal representation makes evident how new concepts are generated from a few concepts taken as self-evident, namely the counting number 1 and the idea of a successor number in the case of arithmetic and the positions and relations of the Family Space and the idea of the kin term product as a way to construct a new kinship relation in the case of kinship systems. The formal representation lays the foundation for exploring the interplay of kinship with other domains whose cultural properties are expressed using kinship concepts.

Kinship Terminology

This article is a revision of the previous edition article by N. Evans, volume 12, pp. 8105–8111, © 2001, Elsevier Ltd.

Abstract

Kinship terminologies consist of the terms used to reference culturally recognized kinship relations between persons. These terms have been assumed to identify categories of genealogical relations (despite ethnographic evidence to the contrary), and kinship terminologies are classified using differences in genealogical referents of kin terms. Recent analysis, however, by building on ethnographically validated procedures for computing kin relations from kin terms without reference to genealogy makes evident the underlying generative logic for the structure of kinship terminologies. Making the generative logic of terminologies explicit provides a more rigorous comparative basis for the study of kinship terminology systems.

Introduction

All societies have terms that are used to address and to refer to one's kin (*see* Kinship in Anthropology). Address terms are the expressions used to address a person during social discourse that reflect the kinship relation between speaker and listener. Multiple terms can be used within a society for the same kinship relation, with the word form varying according to the aspect of the relationship between speaker and listener being identified by the address term. Using an address term presumes the parties involved already know the kinship relation between them. English speakers, for example, might address the woman who has the kinship relation of *mother* to speaker by mom, mommy, mother, mama, ma, mum, mummy, and so on, depending on the age of speaker and the emotional relationship between speaker and listener being foregrounded in their conversation.

Terms of reference, in contrast, overtly express the kinship relation understood to apply between the individuals of concern. Collectively, the terms of reference used by societal members form what anthropologists refer to as a kinship terminology. By a *kinship terminology* is meant, then, the terms used to refer to, or express, the corpus of culturally recognized kinship relations one individual can have to another individual in a particular society. Kinship terminologies differ from one society to another not only because of language differences, but, what is more important, due to cultural differences regarding the meaning, content, structure, and organization of the kinship relations expressed linguistically through the kin terms comprising a kinship terminology.

A kinship terminology is not just a nomenclature system for the kinship relations recognized in a particular society, as it expresses both the organization of, and conceptual interrelations among, the kinship relations making up a kinship terminology (Leaf and Read, 2012). The terminology linguistically expresses a society's indigenous theory of kin relations through the semantic content of kin terms and through the culturally understood conceptual relationships among the kinship terms. The terminology can thus be viewed as an idea system composed of the conceptual relations structurally linking the terms in a kinship terminology into a conceptually bounded system of kin relations. For this reason, formal studies of kinship aimed at elucidating the kinship ideas and concepts that are part of the cultural milieu of a society focus on the terms of reference making up a kinship terminology rather than the terms of address.

Consanguineal and Affinal Kinship Terms

Within a kinship terminology, there is generally a single term corresponding to each culturally recognized kinship relation, though two individuals may have more than a single kinship relation between them, as occurs, for example, when a male and a female who are already related as kin marry and thereby take on a new kinship relation as well. The corpus of kinship terms making up a kinship terminology is typically divided analytically into two parts: *consanguineal* kin terms based on the assumption that the primary kinship relations are determined through biological procreation (hence kin relations are said to be blood relations) and *affinal* kin terms that designate kinship relations determined through marriage. The division into consanguineal and affinal terms with procreation and marriage the basis for the contrast has, however, led to extensive controversy regarding what is meant culturally by kinship and kinship relations, and is not a satisfactory division. In many societies, kin relations can be established by criteria other than procreation and marriage, such as *sponsorship* (which includes adoption, a godparent relationship, and kinship through suckling (El Guindi, 2011)), a name giving-name receiving relationship, food sharing, or co-residence, among other means (Sahlins, 2013).

For English speakers, the kinship terminology includes the consanguineal terms father, mother, son, daughter, brother, sister, uncle, aunt, nephew, niece, and cousin, and the affinal terms include father-in-law, mother-in-law, son-in-law, daughter-in-law, brother-in-law, sister-in-law – the terms marked with the '-in-law' suffix. Some English kin terms, such as aunt and uncle, are both consanguineal ('my parent's siblings') and affinal ('my parent's sibling's spouse') and therefore said to be defined disjunctively, while the English kin term cousin does not have an affinal form and the English kin term spouse is only an affinal term.

Systematic Study of Kinship Terminologies

Kinship terminologies are universal: there is no society that does not have a set of reference terms used to express the kinship relations recognized in that society. Kinship terminologies vary in the number of terms from about 10 or so to around 30 terms and differ not only in the number of kinship relations that are recognized linguistically, but in the interrelationships among these kin terms. The systematic study of kinship terminologies traces back to the seminal work of Lewis Henry Morgan (1871), in the mid-nineteenth century, who carried out a worldwide study of structural differences among kinship terminologies by asking respondents for the kin terms that a terminology user would employ for each of a series of genealogical relations. The relations were aimed at determining the way the kin terms in a terminology refer to lineal and collateral genealogical relations defined with respect to speaker. Morgan assumed that kinship relations are determined through procreation and marriage, hence a kinship terminology represented a particular group's organization of the domain of genealogically defined kinship relations. Subsequently, anthropologists have generally assumed that kin terms are linguistic labels for categories of genealogical relations determined through procreation as it is culturally understood.

Morgan's systematic study of kinship terminologies began with his interest in the terminology of the Seneca (Iroquois) Indians, as their terminology made kinship distinctions lacking an obvious genealogical basis. For example, rather than having a single term referring just to genealogical mother (as happens with the English term *mother*), the Seneca term *no-yeh'* refers not only to genealogical mother but also to mother's mother's daughter, mother's mother's mother's daughter's daughter, and so on. Thus *no-yeh'* refers both to a lineal relation (genealogical mother) and to collateral relations (mother's mother's daughter, mother's mother's mother's daughter's daughter, and so on), contrary to the English and many other terminologies. (A sexually symmetric pattern occurs with the Seneca term *hä-nih'* used to refer to genealogical father, genealogical father's father's son, genealogical father's father's father's son's son, and so on.) In addition, the terms, *ah'je* and *ka-gä* used to refer to genealogical older sister and younger sister, respectively, were also used to refer to the genealogical daughter of any person referred to as *no-yeh'* or *hä-nih'*; that is, the terminology used the logic among the kin terms that a *ka-yä-wan-da* ('daughter') of a *no-yeh'* ('mother') or *hä-nih'* ('father') is an *ah'je* ('older sister') or *ka-gä* ('younger sister'), thereby expressing, without reference to genealogy, a consistently expressed conceptual relationship among the kin terms *ka-yä-wan-da*, *no-yeh'* or *hä-nih'* and *ah'je*/*ka-gä*. (A sexually symmetric pattern occurs with the kin terms for genealogical son and genealogical older and younger brother.) From the perspective of the kin terms, the category of genealogical relations associated with these kin terms derives from this logic expressing the relationship among the kin terms and not the reverse.

Classification of Kinship Terminologies

Most kinship theorists consider that genealogy is the foremost driver of kinship relations and so the terminology linguistically expresses their conceptual organization of genealogical relations, and so the terms are linguistic labels for a priori categories of genealogical relations. The Seneca pattern of including both lineal and collateral genealogical relations under the same kin term – a pattern that occurred in a number of other terminologies elicited by Morgan through his schedules – led him to refer to terminologies that systematically included collateral with lineal genealogical relations as *classificatory terminologies* and all other terminologies that distinguished lineal from collateral genealogical relations, such as is the case with the English terminology, as *descriptive terminologies*.

Early kinship theorists expanded on Morgan's two part typology, culminating in George Peter Murdock's (1949) extensive, comparative work that led to a six part typology still widely used today, based on shared genealogical features in ego's generation. Each of his six types is named for a society whose terminology is an exemplar of that type. Murdock divided the descriptive terminologies into Sudanese (also known as *bifurcate collateral* due to paternal and maternal genealogical cousins being terminologically distinguished) and Eskimo (also known as *lineal* due to all genealogical cousins having the same term and distinguished from genealogical siblings). The classificatory terminologies were divided into Hawaiian (also known as *generational* due to genealogical siblings and cousins not being distinguished), Iroquois (also known as *bifurcate merging* due to genealogical parallel cousins (see below) being distinguished from genealogical cross cousins (see below) and grouped with genealogical siblings), Crow (a bifurcate merging terminology in which the same term is used for genealogical father's sister and father's sister's daughter), and Omaha (a bifurcate merging terminology in which the same term is used for genealogical mother's brother and mother's brother's son). Subsequently, Iroquois has been divided into Iroquoian versus Dravidian terminologies (the latter used by Dravidian speakers in southern India) based on different ways in which genealogical parallel and cross relations are recognized in the terminology.

Parallel and *cross relations* refer to two patterns for the sex of sequential, genealogical positions in a genealogical pathway connecting ego and alter, with kinship relations having the same pattern being given similar sociological treatment by the users of the terminology. For example, many terminologies distinguish between a genealogical *parallel cousin*, who is the genealogical offspring of anyone referred to as a 'brother' of a 'father' or a 'sister' of a 'mother' (sometimes referred to, but incompletely, as 'the offspring of the same sex sibling of a parent') and a genealogical *cross cousin*, who is the genealogical offspring of anyone referred to as a 'brother' of a 'mother' or a 'sister' of a 'father' (sometimes referred to, but incompletely, as 'the offspring of the opposite sex sibling of a parent'). When the parallel/cross distinction is recognized in the terminology in the parental generation, parallel cousins are usually included terminologically with siblings, hence, from a sociological viewpoint, they are not marriageable under an incest taboo forbidding marriage with siblings, whereas cross cousins may be prescribed as the ideal choice for marriage partners.

Other terminology types have been distinguished when other patterns for differences among kinship terminologies have been recognized. While Murdock's typology has helped organize the variety of kinship terminologies, it is also widely

recognized as being inadequate as it assumes similarity in the categorization of genealogical relations in ego's generation implies similarity in the categorization of all other genealogical relations. Using Murdock's criteria, for example, the terminology of the !Kung San, a hunter – gatherer group in northwest Botswana, is classified as an Eskimo type of terminology along with the English terminology, yet except for having a single term for all genealogical cousins, the !Kung San terminology has little resemblance to the English kinship terminology.

Relationship between Terminologies and form of Social Organization

Part of the motivation for organizing the worldwide corpus of kinship terminologies was the assumption that kinship terminology variation would relate to variation in forms of social organization, especially differences in marriage systems. Evolutionary schemes for past systems of social organization were hypothesized, assuming that current kinship terminology distinctions reflected past forms of social organization and associated marriage rules (*see* Kinship, Evolution of). Superficially, bifurcate merging terminologies appeared to correlate with unilineal descent systems, at least when a society had a moiety form of social organization in which the society is divided into two exogamous descent groups. (A descent group consists of all persons who trace through genealogical parents of the same sex to a recognized ancestor when tracing is through genealogical fathers or to an ancestress when tracing is through genealogical mothers.) With descent groups, a man and his terminologically identified brothers are in the same descent group and similarly for a woman and her terminologically identified sisters. With a moiety system, a person's parallel cousins are in the same descent group as that person, hence are not marriageable, whereas that person's cross cousins are in the opposing moiety, hence marriageable. Thus there are parallels between a bifurcate merging (classificatory) terminology with a cousin marriage rule and a moiety form of social organization, but neither bifurcate merging terminologies nor cousin marriage rules are restricted to societies with a moiety form of social organization and each may occur in societies without organization as descent groups. As Rodney Needham concluded, the "assumption that societies with similar terminologies … are thereby sociologically similar" (1971, p. 22) does not hold up to ethnographic evidence.

Absent a connection between terminology and social system through genealogy, there is no need to assume genealogy is the basis of kinship relations. Numerous ethnographers have commented, for the group they are studying, that kinship and kinship relations are far broader and richer than what is implied under the assumption of kinship relations being created through procreation – even when taking into account the cultural construal of procreation – and then expressed through genealogy.

Genealogical Hypothesis and Kinship Terminologies

Early challenges to this genealogical assumption considered kin terms to identify social categories determined through commonality in social relations. The social category argument logically collapsed under Floyd Lounsbury's (1965) formal demonstration, using rewrite rules, of the genealogical logic underlying the Trobriand Islander's kinship terms, contrary to Edmund Leach's (1958) claim that their terminology made no sense from a genealogical perspective and could only be understood as identifying social categories that were part of their social system. (Rewrite rules (Lounsbury, 1964) specify, for the genealogical definition of a kin term, how the primary genealogical relation in that definition may be rewritten to obtain the other genealogical relations in the kin term definition.) Lounsbury's formalism, however, had a critical flaw; he had to assume that each of the kin terms in classificatory terminologies had a primary genealogical meaning that was then extended to other genealogical relations. This *extensionist hypothesis*, though, leads to circular arguments since the hypothesized extensions lack cultural grounding. The hypothesized extensions are neither recognized as such by the users of the terminology, nor are criteria given establishing when one society will make use of the hypothesized extensions in its kinship terminology and another will not. Why English speakers, for example, do not make use of the hypothesized extensions but the Trobriand Islanders do so, is not accounted for.

The genealogical assumption for kinship terminology systems was subsequently criticized extensively by David Schneider (1984) because, he argued, it reflected a western, folk science based on genitor viewed as physical father and genetrix as physical mother and not universal properties of kinship systems. Schneider's critique led to the extreme position of denying that kinship existed as a culturally salient analytical category, despite the fact that all societies make a fundamental social and conceptual distinction between kin and non-kin. What Schneider identified, however, was not the nonexistence of kinship, but of kinship universally derived from relations determined through procreation and expressed using biologically grounded genealogical criteria. Schneider recognized that kinship should be seen in a manner other than through the genealogical lens that had been used since the time of Morgan, but he neither identified what that different lens might be nor recognized that an alternative to assuming the primacy of genealogy for understanding kinship relations was being developed at the same time he was critiquing the assumption of a genealogical basis for the kinship relations expressed through the kin terms making up a kinship terminology.

Structural Logic of Kinship Terminologies

Missing from the genealogical assumption of kinship terminologies has been a way to account for the structural logic whose existence was made evident through the formalism of the descriptive system of rewrite rules discussed by Harold Scheffler and Floyd Lounsbury (1971). Their work made it evident that kin terms are logically interrelated, but failed to identify its underlying structural basis. In a paper published in the 1970s, Murray Leaf (1971) showed that it is possible to elicit a kinship terminology without making use of the genealogical method of elicitation developed by W.H.R. Rivers (1910[1968]) and used extensively in ethnographic research on kinship terminologies. Leaf showed how he was able to

elicit the kin terms of the Punjabi terminology through the kind of kin term calculations that have been widely reported in the ethnographic literature as the means by which users of kinship terminology systems compute kinship relations without reference to genealogy. Two persons can compute the kinship relation they each have to the other simply by each person knowing his or her kinship relation to a third person, even absent knowledge of the genealogical connections among these three persons and without needing to know the genealogical definitions of the kin terms.

The computation is essentially like the computation discussed earlier for the Seneca kin terms. More precisely, and illustrated here with the English kinship terminology, if person A does not know his kin relation to person C, but person A (properly) refers to person B as, say, *uncle* and person B (properly) refers to person C as, say, *daughter*, then from those two kin relations person A, as a user of the English kinship terminology, knows to (properly) refer to person C as *cousin*, without needing to know the genealogical relations involved, if any, among persons A, B, and C (C might be the adopted daughter of B), and without needing to know the genealogical definition of the English kin terms *uncle*, *daughter*, and *cousin*. We may refer to an indigenous calculation of this sort as a *kin term product* (Read, 1984) and write the equation: *daughter* of *uncle* is *cousin* (or more formally, *daughter* o *uncle* = *cousin*, where 'o' stands for a binary product operation). Beginning with the primary kin terms that relate to family relations, the kinship terminology may be elicited by first using kin term products of the primary terms to elicit nonprimary kin terms and then by using products of the primary terms with any elicited terms until no more terms are elicited. The result of the elicitation may be shown as a graph, referred to as a *kinship map* when the graph shows the outcome of the process of eliciting kinship relations, or as a *kin term map* when the graph shows the formal relations among the kin terms expressed through the kin term product equations obtained through the elicitation process (see Figure 1). The kinship map and the kin term map are isomorphic data models showing the structure of the kinship terminology that results from the structural logic embedded within the terminology. The rewrite rules developed by Lounsbury are a consequence of this structure, but the structure is not evident from the rewrite rules.

Generative Basis of Kinship Terminologies

By making explicit the structural form of a kinship terminology, we can then analytically determine its generative basis, if any, by determining, if possible, the generating kin terms for the structure and the structural equations underlying its form, with the requirement that the generating terms and structural equations have cultural saliency, as the goal is not a formal

Figure 1 Kin term map for the American Kinship Terminology, based on the primary kin terms father, mother, son, daughter, and spouse. Male terms are blue, female terms are red, and neutral terms are black. Etc indicates that the kin term map continues in the same way without any structural changes.

representation, per se, but a formal account of the cultural kinship knowledge embedded within a kinship terminology (Read, 2007; *see* Formal Models of Kinship). Thus this analytical method is based on a falsifiable theory about a cultural domain, namely that kinship terminologies have a logically consistent and culturally salient structural form (Leaf and Read, 2012). Failure to find a culturally salient set of generating kin terms and structural equations for the structure shown in a kin term map would falsify the universality of the theory. To date, no counter examples have been found.

Structural Properties of Kinship Terminologies

The structural analysis of kinship terminologies has consistently found structural equations that are culturally meaningful and ethnographically justified. The analysis also makes evident the extent to which properties of a kinship terminology are determined by its internal logic versus considerations external to the terminology. For example, the distinction between descriptive and classificatory terminologies is structurally the consequence of which one of two ways that a sibling relation may be conceptualized is culturally salient: (1) a sibling is the *other child* of one's parents or (2) siblings have the *same parents*. The first concept implies that the kin term referring to the sibling relation is a derived kinship concept: *child* o *parent* = *sibling*, where the instantiation of a kin term product is understood to exclude the speaker. The second implies that the kin term referring to the sibling relation is a primary kin term and corresponds to societies in which sibling relations are central in the domain of kinship relations. The first concept also implies that sibling is not a generating term and a parent kin term (sex-marked in most terminologies, but not in the English terminology) is the primary (consanguineal) generating term. This leads to the descriptive terminologies. The second concept implies that sibling is also a generating term, which then leads to the classificatory terminologies. The second definition for a sibling relation also provides the logical basis for A.R. Radcliffe-Brown's (1950) *equivalence of siblings*, proposed by him as a way to account for the pattern of kinship relations for genealogical mother and genealogical father found in the Seneca and other classificatory terminologies. Radcliffe-Brown, however, did not account for when the equivalence of siblings was culturally salient; we now know that it is culturally salient when their concept of siblings corresponds to the second concept given earlier.

By working out the structural basis of kinship terminologies, we can distinguish the features that are the consequence of its generative logic, such as having kin terms that distinguish between older and younger sibling, or are due to distinctions embedded in the kinship terminology for social and cultural reasons, such as a distinction between older and younger mother's brother in the Tongan terminology that relates to patterns of inheritance (Bennardo and Read, 2007). In addition, rather than assuming features of terminologies are simply added to or removed from a terminology in an evolutionary account, change in features must be related to changes in the structural logic of the terminology (*see* Kinship, Evolution of). For example, terminologies in Australia distinguish between older and younger sibling regardless of the sex of speaker, whereas in the Polynesian terminologies the older/younger distinction generally depends on whether the sibling is a parallel (same sex) or a cross (opposite sex) sibling with regard to speaker. This difference is a consequence of differences in the structural logic of the terminologies from these two regions and so an evolutionary account linking these terminologies must be formulated at the level of changes in the structural logic of terminologies. Using a structural logic approach also makes it possible to form a typology of kinship terminologies based on differences in their respective sets of generating terms and structural equations (Read, 2013a), thereby clarifying what are structurally feasible evolutionary changes in kinship terminologies, as has been shown for the Polynesian terminologies (Read, 2013b). The evolutionary pathway of the Polynesian terminologies determined through their structural analysis is consistent with the work by historical linguists on changes in the word form of the kin terms, but requires different root terminologies for the Polynesian and Oceanic terminologies than the one posited in historical linguistic accounts.

Conclusions

Historically, the study of kinship terminologies began with the assumption that they are mainly names for genealogical categories whose origin is external to the terminology (*see* Family and Kinship, History of). Kinship relations were assumed to be determined through procreation and expressed genealogically. This approach left unspecified how the categories were determined and has been contradicted by ethnographic research that repeatedly finds that kinship ideas and kinship systems are not based in an obvious way on genealogy (which is not to say that kin terms do not relate to genealogy as it is always possible to provide genealogical definitions of kin terms in a post hoc manner). Reaction against the genealogical hypothesis led to the untenable assumption that kinship does not exist, rather than viewing kinship terminologies as cultural objects in their own right. The latter makes it possible to identify the structure embedded in a kinship terminology by identifying the way the kin terms are interrelated through the culturally salient kin term product. This, in turn, has led to analytical determination of the generative basis of the structure of a kinship terminology, thereby bringing the formal analysis of kinship terminologies back to the ethnographic study of kinship systems and the meaning of kinship relations. The analytical approach that has thereby developed makes possible a vibrant and deep-seated understanding not only of kinship terminologies as the expression of the kinship ideas of a particular society, but more broadly of what is meant by culture as a constructed reality, for the kinship terminologies of human societies are cultural constructs through which a kinship domain is formulated that is not the codification of already existing patterns of behavior. The analytical study of kinship terminologies now has the potential of making evident the interrelationship between kinship and social systems in a sound and rigorous manner.

Abstract

This article provides a short biography of the psychoanalyst who has had, after Freud, more impact than any other. It traces her moves from Vienna to Budapest to Berlin and, finally, to London, where she spent most of her professional life. Klein was a founder of one branch of child analysis. She took seriously Freud's hypothesis of the death drives. She also developed an original developmental theory, in which the child's major psychic task is the management of anxiety arising from destructive fantasies and wishes and from virulent envy. In the first, paranoid-schizoid, position, persecutory anxiety is prominent and splitting the major defense. Later, depressive anxiety and the fear of harming the loved object accompany the depressive position. Klein theorized the internal world, and the processes of splitting, projection, and introjection that create that world. Throughout life these are the challenges facing any human being as well as shaping and undermining social formations and processes. The central datum of Kleinian theory is unconscious fantasy.

Within psychoanalysis worldwide, Melanie Klein has had more impact than any other psychoanalyst besides Freud. Her wide-ranging contributions not only reshaped psychoanalytic understandings of mental life; they also have fundamental import for social scientific understandings of human action and the creation of meaning. That Klein is indisputably the most important psychoanalyst after Freud also points to the unusual prominence and participation of women in psychoanalysis from almost the beginning (see Chodorow, 2000).

Born in Vienna on 30 March 1882, Melanie Reizes Klein moved to Budapest in 1910, where she began to read Freud. She entered analysis and analytic training under Freud's colleague Sandor Ferenczi (on Klein's biography, see Grosskurth, 1986; Segal, 1979). She moved to Berlin in 1921, joining the Berlin Psychoanalytic Society and entering analysis with Karl Abraham. Her first formal work as a child analyst began in Berlin. At the invitation of Ernest Jones, Klein visited London in 1925 to lecture on child analysis, and she subsequently moved to England in 1926. Until her death in London on 22 September 1960, she was an active clinician, a leading and innovative child analyst, and a prolific writer who had many followers and colleagues.

Understanding Melanie Klein's life requires an understanding of the history of psychoanalysis. Klein had no direct contact with Freud, but was trained and supported by Ferenczi, Abraham, and Jones, the leaders of the main psychoanalytic centers outside of Vienna and Freud's most important colleagues. These several centers allowed more possibility for independence of thought and action than Vienna itself. While Klein was pioneering the practice and theory of child analysis in Berlin and London in the 1920s, Anna Freud was engaged in a parallel project, based on somewhat different understandings and methods, in Vienna. After Freud developed cancer in 1923, he came to depend almost entirely on his daughter as both professional heiress and personal companion and caretaker. Klein's theory, technique, and stature as a child analyst directly challenged Anna Freud's primacy in this same arena, and Freud was drawn to support his daughter. Thus, even as Klein considered herself the true theoretical heir to Freud, her work from the outset was strongly contested by Anna Freud and her father.

As a result of the Anschluss of March 1938, in which Hitler, with the approval of many Austrians, seized and incorporated Austria into Nazi Germany, the Freuds moved to London, thereby setting the stage for a confrontation and theoretical and organizational sharpening of differences. Freud died in 1939, but the followers of Anna Freud and those of Melanie Klein in London spent the latter war years in 'Controversial Discussions' (King and Steiner, 1991), with an 'Independent' Group holding a middle ground and developing its own theories. Debate posed Klein's espousal of Freud's late instinct theory, with its focus on aggression, her theories of early infant development, her advocacy of the analysis of very young children, and her insistence that the analysis of children (and adults) should begin immediately from interpretation of unconscious fantasy, against Anna Freud's focus on ego defenses and ego functions, her following of the traditional structural and libidinal phase theories, and her advocacy of analyzing from the most surface layer of defense rather than from the deepest layer of unconscious fantasy. The result of the 'Controversial Discussions' was a settling in of a Kleinian Group, led by Klein until her death and still an active force in British psychoanalysis (Spillius, 1988 includes writings on theory and technique by Klein's students and later colleagues).

Since the 1940s, no psychoanalytic center has developed without grappling with Klein. Kleinians continue to be central to British psychoanalysis, and Kleinian thinking has shaped psychoanalysis throughout Latin America. Kleinian ideas were initially anathema in the USA, where emigre analysts were closely allied with Anna Freud, but since the 1980s, Kleinian thinking has become widely influential. In Europe too, psychoanalytic theory grapples with, accepts, or challenges Klein.

Kleinian theory is a complex, intertwined whole resting on several foundations (see Klein, 1975). This account focuses on Kleinian theory rather than on Klein's founding contributions to child analysis and psychoanalytic clinical technique. As a psychoanalyst, Klein like Freud begins from the discovery and investigation of the dynamic unconscious, the postulate that conscious thinking only expresses a small fraction of what goes on in the human mind. The beginning datum of Kleinian theory is the psychic reality, or internal reality, of what Klein

called 'unconscious fantasy.' The dynamic unconscious consists of repressed or split off fantasies that have a powerful effect in shaping conscious life, feeling, and behavior. Unconscious fantasy operates from the very beginning of life and consists of affect-laden stories or proto-stories about the self, the body, and one's relation to others. These stories are not linguistic or narrative, but are forms of implicit knowing and being that portray in direct, unmediated, affectively charged ways, a mental picture of an inner world of self and others. Klein described how this internal reality is created and its constituent effects on all bodily experience, interpersonal relations, and social and cultural experience (for an extended reading of Klein along these lines, see Chodorow, 1999b). It is an 'object-relations theory,' picturing the self, or ego, in relation to others, or objects. Klein's method of play analysis and work with very young children led her to a 'developmental theory' based on changes in prevalent unconscious fantasies. The management of anxiety about 'aggression' in self and others is a central goal of most unconscious fantasy.

Although Freud discussed the ego's relations to its objects and the effects of the object upon the ego – for instance, in his claim that the ego contains a history of object choices – Klein is considered the original object-relations theorist. For Klein, the ego is object-related from birth, all drives are directed toward objects rather than toward gratification and release, and all psychological life revolves around internal pictures of the ego in relation to its objects. Objects are both external – actual people like mother, father, or analyst with whom the self interacts – and internal, parts of the outside world that are unconsciously experienced as within the self. Objects in this 'internal world' may be 'part-objects' – an aspect of another, a body part of another, like the mother's breast or a fantasy of her inside organs – or 'whole objects' – others in all their different aspects. Psychic life especially consists in the building of an internal world through what the ego does psychologically with objects, using such mechanisms as 'splitting,' 'projection,' and 'introjection.' Through these processes, internal and external realities are continuously recreated in relation to one another.

Whereas for Freud, repression of unacceptable thoughts and feelings is the key defense, for Klein, splitting, introjection, and projection are the central defenses. Klein's developmental account revolves around the uses of these defensive processes. In the 'paranoid-schizoid position,' the self and the earliest internal objects – initially the mother's breast, and throughout life, objects that represent the breast – are psychically experienced as either all good or all bad. The ego's goals are to keep bad and good parts of the self and object separate. The ego attempts to preserve its own goodness by keeping good, or loved, objects within, and ejecting and rejecting bad, or hated, objects. 'Projective identification' then leads the ego to feel that the object, now containing bad parts of the self, is persecutory. To control the now persecutory objects, they may be reintrojected, in turn bringing hatred back into the self, which projects badness back into the object. And so on. Split-off good feelings and parts of the self may also be defensively projected into the object, so that the self can feel protected and loved. 'Persecutory anxiety' – the fear of being attacked by bad objects or of annihilation of the self – is the dominant anxiety of the paranoid-schizoid position and leads to the spiral of splitting, projection, and introjection that characterize it. The paranoid-schizoid position is paranoid because of the fear of attack it contains and schizoid because it is based on separating different aspects of the self and the other.

When the child reaches the 'depressive position,' he or she recognizes people as whole objects and painfully realizes that an attack on the bad object is also an attack on the good one, since they are one and the same. Guilt arises, along with the desire to make 'reparation.' Reparation is one root of creativity throughout life as well as of the desire to parent and take care of others. 'Depressive anxiety' – the fear that one will damage the good object – is the characteristic anxiety of the depressive position. Unlike Freud's libidinal stage theory, Klein's theory of positions is not a stage theory in which the achievement of the depressive position involves the giving up of the paranoid-schizoid. All people who have reached the depressive position continue throughout life to move between the two positions.

A complex inner world of self and objects constitutes unconscious fantasy and is the basis of 'transference.' For Klein, transference is not just the putting of early feelings about a parent onto the analyst but a total way of being in the world. Although it is mainly investigated in analysis, transference gives meaning to and animates all experience. It functions as an internal prism through which the world is perceived, becomes subjectively meaningful, and is an object of action. Klein, and especially later Kleinians, also show how forms of thinking themselves transferentially express psychic structure and psychic fantasy, for example, whether a patient can make connections among thoughts, can keep anxiety-laden ideas in mind or must split them off and evacuate them, can keep ideas whole or must destroy or fragment them, can take in ideas from the analyst, can symbolize generatively, and other similar processes.

For Klein, the most anxiety-laden and intolerable unconscious fantasies concern aggression. Klein holds to the later Freudian dual-drive theory, rejected by many analysts, of the life and death instincts. The death instinct constitutes a threat of annihilation or fragmentation from within, creating basic existential anxiety from the beginning of life. The basic wish of the psyche is to get rid of this threat, leading to the projection that creates the first bad object. Persecutory anxiety thus arises originally as a direct response to the internal threat of destruction from within and thereafter also in response to the aggression that has been through projective identification put into objects. The paranoid-schizoid and depressive positions are both organized largely in response to anxieties generated by these fears of annihilation, aggression, and hatred that emerge from self and object.

A major manifestation of the death instinct is found in envy, which Klein describes as the most toxic emotion. Klein discovered the importance of envy in patients' attempts to destroy and dismantle the help offered by the analyst. Envy originates in the perception that the other possesses and enjoys something good and desirable – originally imaged as the creativity, fullness, and bounty of the maternal breast. The envious impulse is to spoil or destroy that goodness. Envy is felt especially virulently against those who appear not to be envious, those who can enjoy creativity and happiness in others. The envious cannot feel gratitude or serenity, and in fact

envy is perhaps the least tolerable of emotions, because its goal is to destroy or spoil not that which is bad, but that which is good. Envy is manifested in attempts to destroy the offerings of parents, of teachers, of analysts, of any whom seem contented and happy. In literature, Iago represents envy in its purest form.

Although she did not explore these implications herself, Klein's work has profound implications for social science (see e.g., Chodorow, 1999b). Klein's account of unconscious fantasy and transference challenges the sociological assumption that the material or structural reality of politics, society, and culture come first and create or determine human life. By documenting how people create the subjective meaning of the world from within, through the dynamics of unconscious fantasy, and how perception, action, and thought result from a transferential shaping that has real effects, Kleinian theory demonstrates that action in the external world is not only taken through the conscious, rational assessment of options, nor is it determined through structural or material constraints. Action is as much a result of an internal, psychologically created picture as of society or culture, and meanings are as much created psychodynamically through affectively charged fantasy as they are culturally presented.

Splitting, projection, and introjection are psychological mechanisms that characterize many social processes. Many of the major political events, crises, and controversies of our time can only be fully understood if the operation of rage, splitting, projection, and introjection is taken into account (see Chodorow, 1998). For example, political and cultural demonization of the enemy is psychologically based on projection and introjection, in which all good resides in the nation, the ethnos, the group, or the political party, and all bad resides in those who are not part of this group. Splitting bad from good, and containing all good within the self while putting all bad into the other, underpins all virulent racism, nationalism, ethnic conflict, and attempts at ethnic cleansing or genocide. Splitting may also be used to ward off elements in the self that are threatening because they are too attractive. Thus, misogyny and homophobia express splitting, projection, and denial, in this case of misogynist and homophobic men's feminine identifications or desires for other men – attractions and desires that are too anxiety-laden to be contained within the self. Finally, Klein describes the great envy of women's creative insides and the psychic threat of images of the mother who contains everything good and powerful – babies, milk, the father's penis, and the ability to give and take life. Such images of maternal power and the mother's body help to explain the psychological intensity of abortion politics and perhaps the extreme violence of a few anti-abortion activists (for a brief overview of Kleinian theory in relation to gender, see Chodorow, 1999a).

Kleinian theory is therefore a basis both of a theory of psychoanalytic treatment and a description of how the human mind develops and operates. It describes how people create themselves and give the world subjective meaning. It explains motivations for action and perception. It is thus an essential component of all investigations of society, politics, and culture.

Abstract

The anthropology of knowledge concerns the categories and organizing concepts through which people make sense of, and act on, their social and natural environments. It is the study of the connections between social organization and content in cultural traditions – a key problem in social thought since the emergence of the social sciences in the nineteenth century. Since the late twentieth century, the complex links to cognition and brain science have further enriched explanations of how knowledge is perceived and communicated.

The anthropology of knowledge concerns the categories and organizing concepts through which people make sense of, and act on, their social and natural environments. It is the study of the connections between social organization and content in cultural traditions – a key problem in social thought since the emergence of the social sciences in the nineteenth century. Since the late twentieth century, the complex links to cognition and brain science have further enriched explanations of how knowledge is perceived and communicated.

With the overall framework of the anthropology of knowledge, some scholars have been concerned primarily with the ethnographic analysis of particular social and cultural groups, the relationship between their beliefs and social structure, and how some bodies are made to appear more central and legitimate than others – as in colonial and authoritarian settings.

Beginning in the 1970s, the anthropology of knowledge increasingly included a concern with how culturally valued cognitive styles – sets of basic, implicit master patterns of language and thought on the basis of which other patterns of knowledge are subsequently acquired – were defined and transmitted. It also focused on how these patterns of knowledge shape, and in turn how they are legitimated by, configurations of power and economic relations among groups and classes in different societies.

Since the late twentieth century, emphasis has shifted from the anthropological study of classification and categorization within cultural traditions – and debates over what is common to humankind and other species – to the relationship between the means of communication and the content of cultural traditions and to how socially valued knowledge is produced and made to seem legitimate and natural to some but is imposed on others – as in colonial settings. This 'thinking about knowing,' as the anthropology of knowledge has recently been called, necessarily engages anthropologists to collaborate closely with brain scientists, biologists, and neuroscientists in addition to historians and philosophers (Marchand, 2010). Memory and forgetting does not work the same way for groups as it does for individuals; groups make memories through food, body sculpture, landscapes, rituals, and monuments (Assmann, 2011).

First Approaches: The Late Nineteenth and Early Twentieth Centuries

Most nineteenth century formulations of the problem of knowledge focused on what entire social groups shared, both those depicted as intensely local and embodied and those shared beyond the limits of particular societies. Thus, representations of aboriginal Australian knowledge depend on seeing landscapes firsthand and on adults who have reached a certain status in their life cycle in which they can impart to others how features of the landscape were created during the Dreaming by the "transformational acts of creative beings" (Tonkinson, 2011: p. 331). Other forms of knowledge, such as geometry and mathematics, were seen as more abstract, not tied to specific peoples and places and more advanced. Earlier formulations of the anthropology of knowledge also implicitly or explicitly assumed an evolutionary schema of social development from elementary to more complex societies, a notion as common to Charles Darwin as it was to Karl Marx. Thus William Robertson Smith (1972), a Biblical scholar whose work profoundly influenced later sociologists and anthropologists, including Émile Durkheim and E.E. Evans-Pritchard, saw a close relationship between the stage of development of a social group and the nature of its intellectual, religious, and moral life. For example, Smith argued that to understand the message of the prophet Ezekiel, the social organization of his time had to be delineated, together with the cosmology and modes of thought contemporary with it. If Ezekiel's prophetic message was found to be different from that of Samuel, Smith argued, it is not because of any contradiction in the Bible but because Samuel addressed himself to groups and situations at different stages of human development.

This dual sense of evolution in history and in the complexity of social forms was basic to Durkheim's *Elementary Forms of the Religious Life* (1915) and his *Primitive Classification* (1963), coauthored with his nephew, Marcel Mauss. Durkheim's goal was to study the most elementary societal forms in order to discern the basic social elements out of which ideas of time, space, causality, category, and person are constructed. Using the example of Australian aborigines, which he considered the best-documented elementary society, Durkheim argued that religious thought, like all forms of thought, derive from collective social action.

Durkheim sought to synthesize the two major prior approaches to categories of thought, the apriorist and the empiricist. The apriorist approach, exemplified by Immanuel Kant, viewed categories of thought as immanent in the human mind. The empiricist approach, exemplified by John Locke, saw these categories of thought as derived from experience, with individuals independently constructing similar perspectives. Mediating between these two approaches, Durkheim argued that categories of understanding were neither innate nor derived from

individual experiences. Instead, they were the product of a collective consciousness created and sustained through shared ritual action. This social basis of knowledge and categorization applied as much to the classification of objects and the natural world as it did to religious thought, at least in elementary societies. This is why the embodied knowledge, as represented by Australian aborigines – connecting landscapes to the Dreaming, to rituals, to perceptions of time and place, and to the relationships among individuals and groups – merited special attention.

For Durkheim, the notion of the collective consciousness (*conscience collective*) joined assumptions of the fundamental faculties of the human mind with the creation of collective representations. Durkheim's argument was elegant, but in synthesizing the main currents of European social philosophy, he was unable to demonstrate the primacy of the social in causing forms of classification. At the least, his argument suggested an analogy between the social order and forms of knowledge, and his psychological assumptions concerning collective representations were quickly superseded. Nonetheless, his work profoundly influenced successive generations of anthropologists interested in the ethnographic representation of cosmologies and religious beliefs and their relation to the social order.

The Ethnography of Knowledge

A classic example of how the work of Robertson Smith and Durkheim influenced ethnographic writing in the first half of the twentieth century is E.E. Evans-Pritchard's study of the Nuer of the southern Sudan (1940). Evans-Pritchard cites neither of these predecessors in his text, although their influence is evident in the structure of his argument. He depicted the Nuer as a cattle-herding people with a simple material life and minimal social and political differentiation, highly dependent on their local environment and seasonal migrations. Evans-Pritchard described these in detail, indicating how ecological conditions shaped Nuer social life and cosmology, or ideas of religion, causality, and the order of things. He showed how the structure of Nuer lineages, age-grades, and political units corresponded to their ideas of time, space, and political relationships.

Like Durkheim, Evans-Pritchard allowed readers to infer that Nuer categories and classifications derived from the structure of their social and political life. As with Durkheim, however, all Evans-Pritchard demonstrated was common schemas or homologies of form among a traditional social structure, ideas of time and space, and cosmology. The anthropological tradition represented by Evans-Pritchard remained dominant through the mid-twentieth century, inspiring other work on cosmology and social structure in other African societies, including John Middleton on the Lugbara of Uganda and Godfrey Lienhardt on the Dinka of the southern Sudan.

The roots of Durkheim's influence continued well beyond mid-century and could be seen in the work of anthropologists such as Edmund Leach and Mary Douglas (1966). Such studies suggest the extent to which people go to maintain or distinguish conceptual kinds and boundaries among animals, plants, genders, foods, peoples, and types of activity. Claude Lévi-Strauss (1966) also focused on the forms of classification implicit in both the kinship structures and in the myths of elementary societies, exploring similarities across cultural traditions that suggested common structures in myths, for example, akin to those studied by structural linguists. Lévi-Strauss's work encouraged a focus on how analogies are made between different cultural domains.

Some anthropologists such as Maurice Godelier (1986) sought to join Durkheimian concerns with categories and classification to a Marxist-inspired linking of ideas of knowledge to modes of production. As with Durkheim's work, however, the emphasis in these studies remained primarily in the classificatory schema implicit in systems of knowledge and in analogies between symbolic representations and material/economic life rather than in how people created, imposed, and altered ways of knowing.

Psychology, Brain Science, and Anthropology

Until the 1920s, the lines between psychology and anthropology significantly overlapped. It was often psychologists more than anthropologists who engaged in comparative work across societies and explored the extent to which humans thought alike. Some anthropologists argued that human intellectual and cognitive processes were essentially similar and varied only with the level of evolution of their culture. Others, such as the French philosopher Lucien Lévy-Bruhl (1857–1939), argued that there was a great divide between the prerational and primitive forms of thought and the rational thought of modern societies. Lévy-Bruhl's (1922) argument had a strong resonance for the French colonial lobby because, with minor adaptations, it even offered to explain the presumed inability of the Muslim societies of North Africa to abandon social forms and beliefs supposedly nonadaptive to the colonial and modern world rather than a form of resistance irrelevant to the presumed great divide between traditional and modern.

After the 1920s, however, there was an increasing disciplinary separation between psychological and anthropological approaches to cognition and knowledge. Psychologists, more than anthropologists, explored issues of cognition and the capacities and processes by which individuals learn, classify, and make associations and analogies. Psychologists thus focused on how the brain is hard-wired for certain thought processes, including the ability to learn languages. Anthropologists dealt more with culturally learned forms of knowledge and classification. Only a few anthropologists such as Gregory Bateson (1972) continued to envision a common ground between the two disciplines.

As Dan Sperber (1985) noted, anthropological work always had two dimensions. Some anthropologists have been more interested in the interpretation and analysis of particular cultural and social groups. Others have been more concerned with the cultural abilities and dispositions of humankind in general. Studies in cognitive anthropology, as the latter focus became known, underscored this distinction. These were the anthropologists most inclined to explore the link with psychology. The 1960s again brought scholars from the two disciplines into close collaboration. In one key study, for example, color perceptions, a domain that anthropologists previously assumed to be culturally transmitted, became recognized as having a more limited range of variation than was initially supposed, suggesting underlying cognitive principles (Berlin and Kay, 1969).

The focus of the Durkheimian tradition of the anthropology of knowledge was always in the outer frame of knowledge – how classificatory schemes for understanding society and the world related to the social order. The work of the cognitive anthropologists studied the order internal to particular schemes of knowledge – such as botany, color, disease types, firewood, and kinship and relationship systems. Michael Cole (1996) called this renewed collaboration between anthropologists and psychologists the second psychology, in which the two disciplines explored the frontier between culture and mind in understanding cognitive development; the acquisition of literacy and numeracy (Wagner, 1993); and language acquisition. In this vein, Dorothy Holland and Naomi Quinn (1987), for example, use the term *schema* to refer to standard learned patterns of activity such as going to the post office by which members of a society learn cultural patterns and habits to accomplish routine tasks, freeing individuals to focus instead on less predictable situations.

Intellectuals

Another component of the anthropology of knowledge is the role of intellectuals in society and the social production of knowledge. Until recent decades, anthropologists were concerned primarily with the bodies of cultural knowledge shared by all members of a society. Anthropologists such as Paul Radin (1957) in American anthropology and Marcel Griaule (1965) in the French tradition portrayed intellectuals as possessing an especially intense awareness of the sacred center of their society and an ability to reflect and explain its categories of knowledge. A classic essay by Victor Turner (1967) about the knowledge and character of one of his principal informants on Ndembu symbolism, comparing him to an Oxford don, also broke from an earlier tradition in which individual producers of knowledge were subsumed in larger collectivities.

An influential approach to defining intellectuals in relation to theories of modernization and modernity was Edward Shils (1972). For him, intellectuals are those imputed with the innate need to understand and articulate ideas and concepts that are more general and profound than those faced in practical, everyday concerns. For Shils, all intellectual work originally arose from religious occupations, but religious orientations in modern times have attracted a diminishing share of the creative capacities of an elite oriented toward more modernconcerns. Shils's approach assumed that not all knowledge was equally shared, and it also encouraged anthropologists and other scholars to think of various types of intellectuals and their relationships with the different political and social contexts in which knowledge is produced and valued. Whether those people were called intellectuals or entrepreneurs, anthropologists shifted their focus away from discerning classificatory categories and cosmologies and toward the economic and political contexts in which knowledge is produced and shaped.

In this shift to understanding knowledge and its social distribution as process and as historically rooted, the strategies used for comprehending elementary societies – to invoke Durkheim's term – were adapted to depict ideas of knowledge in advanced, complex societies. Thus Pierre Bourdieu (1967) compared the cognitive style implicitly learned at the Sorbonne to that transmitted by Bororo elders in the Brazilian Amazon. For Bourdieu, the verbal maneuvers learned by students preparing for the *leçon* at the Sorbonne furnished a model for the 'right' mode of intellectual activity in the French context as much as the dualistic spatial layout of Bororo villages embodied Bororo cosmology as interpreted by dominant elders. The dualistic method of the *leçon*, which establishes a tradition of two views on any subject, is subsequently applied to discussion of a wide range of intellectual problems, to the exclusion of alternative, less culturally valued approaches. But Bourdieu's analogy between the spatial plan of Bororo villages in the Brazilian Amazon region and the cognitive styles implicit in French and German higher learning also contributed to erasing the former assumptions concerning how people think in elementary and advanced societies, with all the assumptions implicit in such terms. Since the 1990s there has been much more emphasis on the shared factors of grounded cognition – an awareness that "the bodily, cognitive, neural, and social mechanisms that permit and constrain knowledge transmission are conjointly operative and mutually contingent" (Cohen, 2010: p. S194). Academic disciplines differ in how much emphasis they place on these different factors, but increasingly they recognize the complex tasks involved in learning to listen, see, weave, perform, and communicate. As Yehuda Elkhana (1981: 27–28) noted more than three decades ago, the notion of a great divide between Western and non-Western, traditional and modern, prescientific and scientific, and literate and nonliterate depended on a distinction between the content and processes of thinking. This distinction is less clear, even in terms of thinking about the European scientific revolution of the seventeenth century. As Elkana notes, one mode of thought was not totally obliterated by the other, and modes of thought have many constituent elements that "shift over time and vary among different cultures."

Knowledge and Power

Bourdieu's work on education, social class, and knowledge in the 1960s linked together several long-standing themes in the anthropology of knowledge but also indicated a shift from earlier concerns with categorization to the practice of creating and distributing knowledge. Bourdieu (1977), like Maurice Bloch (1985), Richard Fardon (1985), Maurice Godelier (1986), and others related knowledge and social classifications to the distribution and control of resources. In the specific case of education in France, Bourdieu depicted how the style and forms of knowledge of French higher education converted social classifications into school classifications, relating mastery of the symbolic classifications and habits of thought of formal schooling to both class and social capital.

The theme of the historical problem of change in dominant ideologies of higher education and how these ideologies were related to the conflicting interests of class and social groups in complex societies was raised at the beginning of the century. Durkheim's (1977) neglected lectures on the evolution of higher education in France are a case in point. It was only by the 1970s, however, that such ideas rose to the forefront of anthropological thought. Studies such as Bourdieu's on higher education in France and others on themes such as the internal logic and changing social context of Islamic ideas of knowledge (Eickelman, 1985) and the process by which

dominant ideas of religion and tradition shifted in Indonesia (Hefner, 1985) joined the long-standing anthropological concern with tacit knowledge in religious experience with how social actors derive meaning from public symbolism and continually shape and renew bodies of knowledge in differing social and historical circumstances.

Fredrik Barth's (1987, 2002) accounts of local variations in the cultural traditions of the Ok of highland New Guinea, like recent multidisciplinary studies of the relationships among minds, bodies, and knowledge, erode the earlier distinction between elementary and complex societies and between implicit and embodied knowledge and explicit knowledge. The Ok use ritual occasions to create and alter systems of knowledge as much as seminars and innovative lectures accomplish the same objective in contemporary Western societies. Departing from earlier accounts such as those of Evans-Pritchard about the Nuer, Barth emphasized the processes of thought and innovation at work within a system of knowledge, producing multiple variations and developments.

Approaches such as Barth's and those of Tonkinson (2011) concerning Australian aborigines also have profound implications for the idea of culture and knowledge. Rather than viewing cultures and bodies of knowledge as implicitly and internally homogeneous, shared, and sharply bounded, they are instead conceived as existing in a perpetually interactive social organization of communication in which individuals reproduce and alter representations and symbols.

Current trends in the anthropology of knowledge thus encompass two related concerns. One approach builds on new collaborations among anthropology, psychology, geography, and other disciplines, exploring new ways of relating public and institutionalized cultural expression to cognition and mental representations (Shore, 1996). The other approach focuses on the social production of knowledge and its relation to power, value, communications, and control. The earlier concern with the values, cosmology, and ways of knowing that are common to all people in a given society has given way to how ideas and innovation are communicated in more bounded and explicit fields of knowledge. Such studies include the diffusion of knowledge and ideas in Silicon Valley, in the genome project, and in biogenetic engineering, and the studies also consider the implications of the new communications media on ideas of religious and political authority. The processes by which change is embodied in implicitly shared ideas of gender and sexuality and of authority and responsibility also form a component of current concerns in the anthropology of knowledge.

Knowledge (Explicit, Implicit and Tacit): Philosophical Aspects

Martin Davies, University of Oxford, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Explicit knowledge is knowledge that the knower can make explicit by means of a verbal statement; implicit knowledge is knowledge that is not explicit. Chomskyan tacit knowledge of rules can be understood as requiring a particular structure in the content-involving explanations of transitions between internal representations. States of tacit knowledge are different from beliefs and states of explicit knowledge in that their content is at least partly nonconceptual. Several applications of the notion of tacit knowledge in philosophical theory are reviewed. Chomsky's notion of tacit knowledge of the rules of a generative grammar provided the theoretical background for research on artificial grammar learning (AGL). Results and disputes in AGL research are reviewed, with particular reference to requirements on testing for conscious versus unconscious knowledge. No test is guaranteed to meet the requirements but tests can be validated if they are used in the context of psychological theories about qualitative differences between conscious and unconscious processes.

Explicit knowledge is knowledge that the knower can make explicit by means of a verbal statement: "Someone has explicit knowledge of something if a statement of it can be elicited from him by suitable enquiry or prompting" (Dummett, 1991). Implicit knowledge can then be defined simply as knowledge that is not explicit. On this construal, implicit knowledge corresponds roughly to what Polanyi (1967) calls 'tacit knowing': "we can know more than we can tell."

Tacit knowing in Polanyi's sense encompasses a variety of phenomena, such as the ability to recognize something (e.g., a person's face) even though one cannot describe in context-independent terms (e.g., without saying, "I know that Bob looks like *this*") how one recognizes it. Polanyi's tacit knowing also includes the holistic diagnostic skills that an experienced and humane psychologist or psychiatrist brings to a clinical encounter. Diagnostic judgment depends on 'context-dependent practical knowledge' (Thornton, 2013).

While explicit knowledge can be expressed and communicated linguistically, Polanyi's tacit knowing cannot be captured in language without reliance on context-dependent or demonstrative elements (e.g., I know that to tie my shoelaces I move my fingers *thus* (in this way)). But tacit knowing can still be communicated and shared. The mechanism of transmission is not telling and understanding, but rather performance and imitation (learning by example). The notion of socially and culturally shared knowledge in the service of solving theoretical and practical problems (perhaps in the form of shared knowledge about what will happen, and about what to do, in various situations) is of evident importance for the social sciences. Specifically, shared theoretical and practical knowledge can be seen to play a foundational role in the establishment and development of institutions (Mantzavinos, 2001; Mantzavinos et al., 2004).

A different notion of tacit knowledge, introduced by Chomsky (1965; see also Fodor, 1968), has been of central importance for philosophy and cognitive science over the last half century, and this will be the focus of the first four sections of this article. An account of Chomskyan tacit knowledge will be given and the relationship between tacit knowledge and other psychological states will be discussed (Section An Account of Tacit Knowledge). Two distinctions that are drawn using the terminology of 'explicit' versus 'implicit' will be explained (Section Representation and Rules: Explicit and Implicit): information that is explicitly stored versus information that is implicitly represented (implied by explicitly stored information) and rules that are explicitly stored versus rules that are implicit in a system ('wired in'). Four examples of the use of the notion of tacit knowledge in philosophical theory will be reviewed (Section Tacit Knowledge in Philosophy).

Chomsky's notion of tacit knowledge provided the theoretical background for empirical research using the artificial grammar learning (AGL) task (Section Tacit Knowledge in Psychology: The AGL Task) and this research program will be described (Section Implicit Learning and Tacit Knowledge of Rules). The primary interest of AGL research for this article is that it makes use of a distinction between conscious and unconscious knowledge – a contemporary rendition of the explicit versus implicit knowledge distinction. Thus, empirical research using the AGL task can be seen as a chapter in the scientific study of consciousness. Theoretical proposals about testing for conscious knowledge will be discussed (Section Conscious and Unconscious Knowledge) and recent work on conscious (explicit) and unconscious (implicit) knowledge using AGL and related experimental paradigms will be reviewed (Section Conscious Knowledge in the Context of Psychological Theory).

Chomsky on Tacit Knowledge of Rules

In a famous passage, Chomsky (1965) said, "Obviously, every speaker of a language has mastered and internalized a generative grammar that expresses his knowledge of his language. This is not to say that he is aware of the rules of the grammar or even that he can become aware of them." This internalization of the rules or principles of a generative grammar is usually described as tacit knowledge and the claim that each language user tacitly knows a generative grammar has been a core element of Chomskyan linguistics and cognitive science (e.g., Chomsky, 1986: "the central concern becomes knowledge of language"). Tacit knowledge in this Chomskyan sense counts

as implicit according to our initial definition, because a speaker who has tacit knowledge of the rules or principles of a grammar is usually unable to provide a verbal statement of those rules or principles. (A student of linguistics may be able to state the rules that he tacitly knows. But, even in this case, the tacit knowledge is not simply transformed from implicit to explicit. The linguistics student's state of explicit knowledge will probably be based in part on reading books and listening to lectures and will be somewhat independent from – not constituted or underpinned by, and not a manifestation of – his or her state of tacit knowledge.)

Chomsky on the Faculty of Language

We have introduced the notion of tacit knowledge as being Chomskyan. But, before proceeding, it is appropriate to acknowledge that, in more recent presentations (e.g., Chomsky, 2000, 2005; Hauser et al., 2002), Chomsky describes his project in rather different terms, and from a 'biolinguistic perspective.'

According to these more recent presentations, the object of study is an individual's internal language (I-language), the attained state of the individual's faculty of language. The faculty of language itself is conceived as a component or organ of the mind/brain, with its initial state (studied under the heading 'universal grammar') fixed by genetic endowment. At the heart of the faculty of language are a collection of primitive items (the lexicon or vocabulary) and a procedure that generates complex structures (expressions) from the lexical items. The faculty of language interfaces with sensorimotor (perceptual-articulatory) systems and with conceptual-intentional systems and each expression, E, is a pair <PHON(E), SEM(E)>, in line with the conception of language as a system of sound–meaning pairings.

It seems clear that, on this account, the attained state of the faculty of language is not a state of explicit or tacit knowledge about the I-language; it is the I-language itself. This attained state of the faculty of language is not a state of knowledge about a set of lexical items and about complex expressions built from those items; rather, it is constituted by the lexicon and the generative procedure themselves. And the procedure generates, not representations of complex expressions, but the expressions themselves.

Someone might suggest that the primary function of language is interpersonal communication and that the internally generated expressions of the I-language should be regarded as representations of external tokens of sentences in communicative use. Consequently, the state of the faculty of language should still be regarded as a body of knowledge – knowledge about external language. But Chomsky would utterly reject that suggestion. Following on from some discussion of remarks by Jacob and Luria, Chomsky (2005) describes the internally generated expressions as "the infinite variety of internal structures that enter into thought, interpretation, planning, and other human mental acts, and that are sometimes put to use in action, including the externalization that is a secondary process if the speculations just reviewed turn out to be correct."

There is some debate as to whether there has really been a radical change in Chomsky's substantive position (Collins, 2004; Matthews, 2006). But, however that may be, many questions arise. For example, even if the attained state of the faculty of language is the I-language, rather than being a body of tacit knowledge about the I-language, subjects still have explicit knowledge about their own languages, and some of this knowledge seems to have a first-person character. If Chomsky is correct, then this first-personal linguistic knowledge cannot be explained in terms of the subject's drawing on states of tacit knowledge embodied in the faculty of language. So one continuing project for foundational research on knowledge of language is to provide and evaluate accounts of first-personal linguistic knowledge that do not appeal to tacit knowledge (Smith, 2008).

With this acknowledgment of the nature of Chomsky's recent descriptions of his project, we return to 'Chomskyan' tacit knowledge of rules.

Quine's Challenge

Quine challenged Chomsky's introduction of the notion of tacit knowledge by making use of the distinction between behavior that is guided by a rule and behavior that merely conforms to a rule. As Quine (1970) used the notion, guidance by a rule requires explicit knowledge of that rule: "the behavior is not *guided* by the rule unless the behaver knows the rule and can state it." In contrast, as the notion of conformity is used here, conformity to a rule does not require knowledge of the rule. Behavior conforms to a rule if it fits the pattern that the rule requires. Thus, a subject can behave in a way that conforms to a rule although his behavior is not guided by the rule: "Fitting is a matter of true description; guiding is matter of cause and effect."

Chomsky's tacit knowledge of a rule is supposed to be less demanding than the kind of guidance that requires explicit knowledge of the rule; but it cannot be equated with mere conformity to the rule. In fact, conformity to a rule is neither necessary nor sufficient for tacit knowledge of the rule. Conformity is not necessary for tacit knowledge, because the psychological state of tacit knowledge of a rule does not guarantee effective use of that knowledge to generate behavior that conforms to the rule. In Chomsky's terms, competence – which is a state of knowledge – must be distinguished from performance. (This distinction between having knowledge and making use of that knowledge holds good for explicit, as well as for tacit, knowledge. Sometimes – all too often – we possess explicit knowledge that is relevant to the task at hand and yet the knowledge is not put to use in our behavior.)

More importantly for present purposes, conformity to a rule is not sufficient for tacit knowledge, because a tacit knowledge claim is not offered as a summary description of a pattern in behavior but, rather, as a putative explanation of behavior. There will always be alternative sets of rules that require just the same behavior for conformity, and thus provide equally adequate summary descriptions of a battery of conforming behavior. But it is part of the idea of tacit knowledge that a speaker's actual behavior might be correctly explained in terms of tacit knowledge of one set of rules, rather than in terms of tacit knowledge of an alternative set of rules to which the behavior also conforms.

Quine (1970) expressed skepticism about Chomsky's conception of tacit knowledge as intermediate between explicit guidance and mere conformity: "Implicit guidance is a moot enough idea to demand some explicit methodology." It is at this point that Quine posed his challenge. He insisted that, if an attribution of tacit knowledge is an empirical claim that goes beyond a summary of conforming behavior, then it should be possible to indicate what kinds of evidence would count in favor of, or against, that attribution. He also insisted that this evidence should involve the subject's own behavior.

Quine's demand is challenging because there is no unique set of rules to which a subject's behavior conforms. But there are two points to be made in response. First, there can be no a priori limit on the kinds of evidence that might be relevant to an empirical claim. So it is not legitimate to restrict evidence that could support an attribution of tacit knowledge to the behavior of the very subject to whom the attribution is being made. Second, the more general point about evidence is a fair one. There should be something to be said about what kinds of evidence would support an attribution of tacit knowledge. But more fundamental than the question about evidence is the question what the correctness of such an attribution would consist in – what a state of tacit knowledge is.

An Account of Tacit Knowledge

We can sketch one kind of answer to this fundamental question about tacit knowledge (Davies, 1987; Evans, 1981; Peacocke, 1989) by using an example that involves, not rules of syntax, but rules of pronunciation for simple three-letter strings. Suppose that there are five initial consonants, 'B,' 'D,' 'F,' 'H,' 'K'; five central vowels, 'A,' 'E,' 'I,' 'O,' 'U'; and five final consonants, 'M,' 'N,' 'P,' 'T,' 'Z,' Thus, there are 125 three-letter strings. Suppose that each letter is assigned a single phoneme by a letter–sound rule, such as the 'B' → /b/ rule: if a string begins with the letter 'B,' then its pronunciation begins with the phoneme /b/. The 15 letter–sound rules logically determine pronunciations for all the 125 strings.

Now consider a person reading these letter strings aloud. Behaviorally, the person produces a spoken pronunciation when a letter string is visually presented; for example, the person produces the pronunciation /bæm/ (rhymes with 'ham') when the letter string 'BAM' is presented. Suppose that this person's behavior – vocally producing pronunciations in response to the visual presentation of letter strings – conforms to the 15 letter–sound rules. We assume that there are psychological processes underpinning this behavior, and that these processes involve transitions from internal representations of presented letter strings to internal representations of to-be-produced pronunciations. These transitions can also be described as conforming to the letter–sound rules: When an input represents a three-letter string, the output represents the pronunciation that is determined by the rules. In this setting, our fundamental question is: What would it be for this person (or, indeed, for a mechanical reading-aloud system) to have (or embody) tacit knowledge of the 15 letter–sound rules?

The answer to this question, in outline, is that tacit knowledge of the rules requires a particular structure in the causal explanations of the transitions from internal representations of letter strings (orthographic representations) to internal representations of pronunciations (phonological representations). Consider first the abstract structure of the logical determination of pronunciations by the letter–sound rules. Each rule (e.g., the 'B' → /b/ rule) makes a common contribution to the logical determination of the pronunciations of 25 three-letter strings (e.g., those beginning with 'B'); and the pronunciation of each letter string is logically determined by three letter–sound rules. Tacit knowledge of the 15 letter–sound rules then requires a causal-explanatory structure that mirrors this structure of logical determination. A state of tacit knowledge of a letter–sound rule makes a common contribution to the causal explanations of 25 transitions from orthographic to phonological representations; and the causal explanation of each transition involves three states of tacit knowledge of letter–sound rules.

Clearly, conformity to the rules is not sufficient for tacit knowledge of the rules according to this outlined account. For example, mere conformity to the rules does not guarantee that there is any common factor in the causal explanations of the 25 transitions from orthographic representations of letter strings beginning with 'B' to phonological representations of their pronunciations (beginning with /b/). Conformity to the rules might be achieved although, for each of the 25 strings beginning with 'B,' the transition from an orthographic to a phonological representation depended on causal processes that were specific to that string.

The Structure Required for Tacit Knowledge

The kind of structure that tacit knowledge requires, in the causal explanations of transitions between psychological states, is not mysterious. Stepping back from internal representations and tacit knowledge for a moment, consider transitions between ordinary conscious beliefs (or states of explicit knowledge) about presented letter strings and conscious beliefs (or, again, states of explicit knowledge) about to-be-produced pronunciations. In particular, consider these transitions in two subjects, Syst and List. Suppose that Syst has explicit knowledge of the 15 letter–sound rules and is able to draw on this knowledge to work out – that is, to infer – the pronunciations of all 125 three-letter strings. For each letter–sound rule, explicit knowledge of it figures as a common factor in Syst's inferences about the pronunciations of 25 three-letter strings and, for each of the 125 three-letter strings, Syst's inference draws on explicit knowledge of three letter–sound rules. Suppose that List, in contrast, lacks explicit knowledge of the letter–sound rules but has 125 separate pieces of explicit knowledge, one for each three-letter string – from explicit knowledge that string #1, 'BAM,' is pronounced /bæm/ through to explicit knowledge that string #125, 'KUZ,' is pronounced /kʌz/ (rhymes with 'fuzz'). We can say that List has explicit knowledge of 125 pronunciation rules, but each of these rules applies to only one three-letter string.

Syst and List assign the same pronunciations to the 125 letter strings, but there are substantial differences in the structure of the causal explanations of their transitions from beliefs about letter strings to beliefs about pronunciations. For example, there is a single psychological state of Syst (namely, explicit knowledge of the 'B' → /b/ letter–sound rule) that

makes a common contribution to the causal explanation of each of Syst's beliefs about the pronunciations of letter strings beginning with the letter 'B.' But there is no such common factor in the causal explanations of List's beliefs. Similarly, the psychological states that figure in the explanations of Syst's beliefs about the pronunciations of some letter strings (e.g., that 'BAM' is pronounced /bæm/ and that 'DEN' is pronounced /den/) are together sufficient to explain Syst's beliefs about the pronunciations of other letter strings ('BAN,' 'BEM,' and four others); but nothing similar is true of List.

These differences in causal-explanatory structure between Syst and List may be manifested in many ways. For example, List may lose (e.g., by forgetting) his explicit knowledge about the pronunciation of just one-letter string (e.g., 'BAM'), while retaining his knowledge about the pronunciations of the other 124 strings. But if Syst loses some of his relevant explicit knowledge and no longer believes that the letter string 'BAM' is pronounced /bæm/, then he will probably also lose his beliefs about several other letter strings (all strings with 'B' as initial consonant, or all strings with 'A' as central vowel, or all strings with 'M' as final consonant). Similarly, List may revise his beliefs about the pronunciations of individual letter strings in a piecemeal way; but Syst is likely to revise his beliefs about the pronunciations of letter strings in a systematic way.

We can use these descriptions of the role of explicit knowledge of rules in Syst's and List's transitions between conscious beliefs to clarify the kind of causal-explanatory structure that tacit knowledge of rules requires. A state of explicit knowledge (e.g., of a letter–sound rule, in the case of Syst) is a state with a particular content and it makes a common contribution to the content-involving causal explanations of many inferential transitions between beliefs; the transitions are explained as transitions between beliefs with their particular contents. In a similar way, a state of tacit knowledge is a state with a particular content and it makes a common contribution to the content-involving causal explanations of many inference-like transitions between representations; the transitions are explained as transitions between states with particular representational properties (Peacocke, 2008). These representations might not be beliefs but, rather, representations or states of information of the kind that figure in information-processing psychology. Indeed, states of tacit knowledge are often states of information-processing systems within a subject – systems whose internal operations are not normally accessible to the subject's consciousness.

In general, a state of tacit knowledge is a state that figures as a common factor in content-involving causal explanations of transitions between representations or states of information. Where different sets of rules require the same transitions for conformity (the case that concerned Quine), the correct attribution to a subject of tacit knowledge of one set of rules rather than another requires a particular structure in the causal explanations of transitions between representations within the subject. For example, correct attribution of tacit knowledge of the 15 letter–sound rules rather than the 125 one-case pronunciation rules requires the Syst-like causal-explanatory structure rather than the List-like structure (Davies, 1987; Evans, 1981; Peacocke, 1989).

Once an account of tacit knowledge in terms of causal-explanatory structure is in place, it is a relatively straightforward matter to give examples of empirical evidence that would count in favor of – and other evidence that would count against – the attribution to a subject of tacit knowledge of a particular set of rules, such as rules of a language. Indeed, some of this evidence meets Quine's additional requirement of concerning the behavior of the subject to whom the attribution is being made. Relevant behavioral evidence could come from experimental studies of language acquisition, language perception, and language impairment following brain damage, while further evidence would be available from neural imaging.

Tacit Knowledge, Beliefs, and Nonconceptual Content

While it is fairly natural to describe tacit knowledge of rules (such as syntactic rules, in Chomsky's example) as a case of 'knowing more than we can tell,' it is also possible to query the appropriateness of the use of the term 'knowledge' here. Knowledge is usually taken to require belief and to be connected with reliability of the method by which the belief is produced and with notions of justification, warrant, or entitlement to believe. Information-processing mechanisms whose operation is not accessible to consciousness may well meet requirements of reliability, and subjects may have an epistemic entitlement to rely on such mechanisms in forming beliefs (Burge, 2003). Thus, a belief in whose production states of tacit knowledge are implicated may be justified or warranted. But states of tacit knowledge themselves fall outside the scope of epistemic justification or warrant because they are not beliefs.

Several considerations may be offered in support of the claim that states of tacit knowledge are different from beliefs. One is that a subject is usually unaware of his or her own states of tacit knowledge and, indeed, unable to become aware of them. But this, by itself, is not clearly decisive because it seems possible to make sense of the notion of an unconscious belief – a belief of which one is not aware, and perhaps even a belief of which one cannot become aware. Second, states of tacit knowledge are limited in their causal role and influence. It is characteristic of beliefs that a belief may figure in many different ways in a subject's thinking, reasoning, and planning, depending on the subject's other beliefs and desires. A belief is "at the service of many distinct projects" (Evans, 1981). States of tacit knowledge, in contrast, are not inferentially integrated with the subject's beliefs (Stich, 1978); they are inferentially isolated, often with causal roles that are limited to an encapsulated and domain-specific information-processing system (a module; Fodor, 1983). However, this again may not be quite decisive, because we can make sense of the ideas of fragmented rather than integrated minds, and of beliefs that are compartmentalized, guiding behavior in only some – perhaps very few – contexts (Egan, 2008). Some monothematic and circumscribed delusions may be beliefs of this kind (Davies et al., 2001).

A third consideration supporting a distinction between states of tacit knowledge and beliefs is that believing requires the possession of concepts. No one can believe that emus do not fly without having some concept of emus and of flying (and

negation). But, in general, the subject who has tacit knowledge of a rule does not need to grasp or possess the concepts that a theorist would use to specify the rule that is tacitly known. This is particularly clear in the case of tacit knowledge of rules of language (e.g., rules of syntax). Every normal speaker has tacit knowledge of such rules but only people who have studied linguistics grasp all of the concepts that are needed to specify the rules. Thus, states of tacit knowledge are psychological states with nonconceptual content (or, at least, with content that is partly nonconceptual). The subject of the state does not need to possess (still less, to deploy) all the concepts that would be required to specify the content of the state (Davies, 1989). Beliefs, in contrast, are the paradigm example of psychological states with conceptual content.

Critiques of Tacit Knowledge

Quine is certainly not the only philosopher to have adopted a critical view of the notion of tacit knowledge as it figures in linguistics, psychology, and cognitive science.

Some philosophers have argued that Chomsky's claims about tacit knowledge involve a conceptual confusion, because the notion of a rule of language belongs with the idea of a normative practice in which people advert to rules to justify, criticize, or excuse their actions (Baker and Hacker, 1984). But the notion of a tacitly known rule should be distinguished from the notion of a rule that figures in a normative practice. Once the distinction is made, there remains an important question about the relationship between the rules that are tacitly known by individual speakers and the normative practices in which those speakers participate. But that question does not indicate any conceptual incoherence in the very idea of tacit knowledge.

More recently, Bennett and Hacker (2003) have argued that the information-processing paradigm that is shared by cognitive neuroscience and cognitive science rests on a philosophical mistake. They say that psychological powers (e.g., perceiving, thinking, feeling) that are properly attributed to whole human beings should not be attributed to parts of human beings. According to this critique, neither the brain (in cognitive neuroscience) nor an information-processing module (in cognitive science) is an appropriate subject of psychological predicates. Here, we should acknowledge that, in the sciences of the mind, systems smaller than a whole human being are credited with psychological states and processes such as inference-like transitions between representations, mediated by states of tacit knowledge. But it is not clear that this is a philosophical mistake, for these psychological attributions can surely be distinguished from attributions of perceptual experiences, thoughts, and feelings. (We have just seen that states of tacit knowledge are importantly different from beliefs.)

It has also been argued that the ideas of tacit knowledge of rules, and of unconscious information processing in general, are problematic because of a deep connection between intentionality (the representational nature of thoughts and beliefs) and consciousness. This critique culminates in the claim that "there are brute, blind, neurophysiological processes and there is consciousness; but there is nothing else" (Searle, 1990). Specifically, according to this critique, there is no unconscious information processing and there are no states of tacit knowledge that are inaccessible to consciousness. But, once again, a response to the critique can begin from a distinction. Even if we accept that there is an important connection between intentionality and consciousness at the level of the whole human being, states of tacit knowledge and representations within cognitive modules are not beliefs, and a philosophical account of their representational nature may be quite different from an account of the intentionality of beliefs. (For a defense of the appeal to tacit knowledge in psychological explanation against an earlier critique (Ryle, 1949), see Fodor, 1968.)

There remain questions about the relationship between the psychological properties of whole conscious human beings – which belong at the folk-psychological or personal level of description – and the information-processing properties of component systems of the mind and brain – which belong at the subpersonal level of cognitive and neural mechanisms (Dennett, 1969). But there is no reason to assume that answering these questions in a way that highlights what is distinctive about the mental lives of conscious persons will require a radically negative assessment of cognitive science (Davies, 2000).

Representation and Rules: Explicit and Implicit

Our starting point was that explicit knowledge is knowledge that the knower can make explicit by means of a verbal statement. Thus, explicitness is a matter of the subject being able to present information in linguistic form; it is not a matter of how the information is stored in the subject's mind or brain when it is not being called upon.

Suppose that someone knows, in the everyday sense of that term, the axioms of some theory. Provided that this knowledge can be verbally articulated, it counts as explicit knowledge. Now consider some theorem that is derivable from those axioms. The person who knows the axioms may well, with some suitable inquiry and prompting, be able to see that the theorem follows from the axioms and to state it verbally. For example, someone who explicitly knows some elementary arithmetical facts may be able to work out, and to state, that $68 + 57 = 125$. On Dummett's (1991) account, this latter piece of knowledge, even though the sum is computed when needed rather than being stored in memory, counts as no less explicit than the stored elementary facts from which it is derived. Indeed, it counts as explicit knowledge even before the knower works it out; for the personal-level notion of explicit knowledge is defined in terms of the possibility of eliciting a verbal statement by inquiry or prompting. Thus, once some propositions are classified as explicitly known, the category of explicit knowledge also includes at least some of the as-yet-undrawn consequences of those propositions.

However, the terms 'explicit' and 'implicit' are also used to mark a number of distinctions that are specifically related to the subpersonal-level storage and processing of information. Two such distinctions are explained in this section.

Inference and Implicit Representation

Dennett (1983) introduced a quite different distinction from Dummett's when he said, "Let us have it that for information to

be represented *implicitly*, we shall mean that it is *implied* logically by something that is stored explicitly." On this usage, the as-yet-undrawn consequences of propositions that count as explicitly stored would be classified as implicitly represented. In fact, relative to any given notion of explicit storage of information, it is possible to define a whole family of notions of implicit representation, differing over the inferential resources that can be used in drawing out consequences from the information that is explicitly stored.

There is no uniquely correct account of explicit storage but one natural idea is that explicit storage involves the use of a language-like code (a subpersonal-level echo of the requirement for explicit knowledge). A second idea that is fairly natural in the context of theories of information storage and processing is that explicitly stored information has to be accessed before it can be used. A problem in accessing stored information may result in a failure to use information that is relevant to the task at hand. Putting the two ideas together, we have a picture in which explicit storage of information is a matter of syntactically structured inscriptions on pages that are not always easy to locate. Drawing out the consequences of explicitly stored information could then be conceived as manipulating inscriptions in ways that are analogous to the formal procedures involved in the derivation of theorems from axioms in a logical system (the computational model of the mind; Fodor, 1987).

Beginning from this notion of explicit storage of information, we could consider information that can be arrived at by deductive inference from information that is explicitly stored. If elementary arithmetical facts were explicitly stored in a person's memory, then the information that $68 + 57 = 125$ would count as being implicitly represented. Thus, the subpersonal-level contrast between explicit storage and implicit representation could distinguish between two cases that would both count as explicit knowledge at the personal level. This deductive notion of implicit representation could be refined by distinguishing, for example, between information that can be arrived at from the explicitly stored information by unrestricted deductive inference, by deductive inference subject to some set of human limitations, or by deductive inference that is within the compass of some specified individual. Alternatively, we could go beyond deductive inference and allow methods of induction (or rule extraction) and abduction (inference to the best explanation). Then, for example, if only facts about particulars were explicitly stored, generalizations or rules that subsumed those facts would count as implicitly represented.

Rule-Explicit and Rule-Implicit Systems

The notions of explicit storage and implicit representation belong with mechanistic theories about the storage and processing of information. These notions could be applied to any information-processing system and they have no special connection with human subjects. Even in the case of human subjects, we have already seen that subpersonal-level explicit storage is not necessary for personal-level explicit knowledge. Explicitly known information might be either explicitly stored or implicitly represented. It is also the case that explicit storage – even explicit storage within a human subject – is not sufficient for explicit knowledge. Information might be explicitly stored within a human subject yet not available to the subject for verbal report, not accessible to the subject's consciousness, and not conceptualized by the subject.

Tacit knowledge of a rule may involve explicit storage of this kind. An internal representation encodes the rule in a syntactically structured format and a process of searching for and accessing that representation is required before tacit knowledge of the rule can contribute causally to any transitions between input and output representations. For example, letter–sound rules could be explicitly stored within an information-processing system for reading aloud words and other pronounceable letter strings (see the implemented computational model of reading aloud described by Coltheart et al., 2001). In such a case, the system is said to be rule-explicit, and there is a clear gap between having tacit knowledge of the rules (that is, having the rules represented in the system) and using that tacit knowledge.

While the account of tacit knowledge in terms of causal-explanatory structure allows for tacit knowledge that is a matter of explicit storage, it certainly does not require that tacitly known rules should always be explicitly stored. A state of tacit knowledge is a state that figures as a common factor in causal explanations of transitions between representations. The use of an explicitly stored rule can figure as such a causal common factor, but so can a component processor (a 'transition mediator'; Peacocke, 1989) within an information-processing system. The transition corresponding to the rule can be 'wired in' to the system, which is then described as rule-implicit (Fodor and Pylyshyn, 1988).

The distinction between rule-explicit and rule-implicit systems is quite different from the distinction (in the previous subsection) between explicit storage and implicit representation of information. Rule explicitness is a matter of explicit storage but rule implicitness (that is, a rule that is 'wired in' to the system) is not a matter of implicitly represented information (that is, information that is implied by what is explicitly stored). Partial analogies for both contrasts can be found by considering a formal theory in which 15 proper (that is, not purely logical) axioms state the letter–sound rules, and theorems specifying the pronunciations of the 125 three-letter strings can be derived. If the axioms are analogous to what is explicitly stored in an information-processing system, then the theorems that are implied by the axioms are analogous to what is implicitly represented.

Each proper axiom makes a common contribution to the proofs of 25 theorems specifying the pronunciations of letter strings and, in the proof of each such theorem, three proper axioms figure. This structure of derivational common factors would be preserved if the theory were formulated, not with 15 proper axioms, but instead with 15 proper rules of inference (e.g., From: String X begins with letter 'B,' infer: The pronunciation of X begins with the phoneme /b/). Derivationally, a rule of inference is a transition mediator and the distinction between proper axioms and proper rules of inference in a formal theory provides a partial analogy for the distinction between explicitly stored rules and rules that are implicit in ('wired in' to) an information-processing system.

Tacit Knowledge in Philosophy

The starting point for this article was Dummett's (1991) definition of explicit knowledge as knowledge that the knower can make explicit by means of a verbal statement. Explicit knowledge was contrasted with implicit knowledge, conceived as Polanyi's tacit knowing, and with Chomsky's tacit knowledge. We have given an account of tacit knowledge as having a characteristic causal-explanatory role: a state of tacit knowledge makes a common contribution to content-involving causal explanations of transitions between representations. States of tacit knowledge are different from beliefs and states of explicit knowledge in that the subject of a state of tacit knowledge does not need to possess all the concepts that would be required to specify the content of the state. We have also explained the subpersonal-level distinctions between information that is explicitly stored and information that is implicitly represented and between a tacitly known rule that is explicitly stored and a tacitly known rule that is embodied in a component processor (transition mediator).

In this section, we review four cases where the notion of tacit knowledge figures in philosophical theory.

Tacit Knowledge of Compositional Semantic Theories

Philosophers of language have an interest in compositional semantic theories for natural languages; that is, theories that reveal how the meanings of complete sentences depend on the meanings of their constituent words and the ways in which those words are put together. In such theories, proper axioms specify the meanings of words and basic modes of combination of words, and theorems that are derivable from those axioms specify the meanings of complete sentences. While it is plausible that ordinary speakers of a natural language have, or can come to have, explicit knowledge of some of these theorems, it is also plausible that ordinary speakers do not need to have, and usually do not have, explicit knowledge of all the axioms of a semantic theory for their language. What, then, is the relationship between an ordinary language user and the axioms of a semantic theory for his or her language?

One possible answer to this question is that the epistemological relationship between the language user and the theory extends no further than the theorems that specify meanings for complete sentences, and that the role of the axioms is merely descriptive. If a semantic theory has just a finite number of proper axioms (one for each word in the language and one for each basic mode of combination), from which meaning specifications for complete sentences can be derived, then those axioms provide a statable summary description of the language user's capacity to understand complete sentences.

Another possible answer makes use of the notion of explicit knowledge of the axioms, but in an indirect way. Davidson (1984) says that a condition of adequacy for a semantic theory is that what it states should be "something knowledge of which would suffice for interpreting utterances of speakers of the language to which it applies." Clearly, if explicit knowledge of the theorems that specify meanings for complete sentences would suffice for interpreting utterances of speakers, then so would explicit knowledge of the axioms from which those theorems can be derived.

Because the explicit knowledge that would suffice for interpretation or understanding is not knowledge that ordinary speakers have, this second answer shares an important property with the first answer. Neither answer proposes a relationship between ordinary speakers and the axioms of a compositional semantic theory that would provide an explanation of the fact that ordinary users of a language are able to understand sentences that they have never encountered before. An explanation of this fact is available, however, if language users have tacit knowledge of the axioms of a compositional semantic theory for their language. If a hitherto unencountered sentence is built out of familiar words in familiar ways, then understanding of the new sentence can draw on the language user's tacit knowledge of meaning-specifying axioms for those words and modes of combination (Evans, 1981; Davies, 1987).

The appeal to tacit knowledge here has an additional theoretical advantage of assigning a determinate meaning even to sentences that will never be used. An alternative solution to the 'meaning without use' problem appeals, not to tacit knowledge, but simply to extrapolation from the used sentences to unused sentences: "Use determines some meanings, those meanings determine the rules, and the rules determine the rest of the meanings" (Lewis, 1992). However, this alternative solution to the problem has an unattractive consequence.

Suppose that a speaker PB uses (or equally, suppose that a population of speakers use) a finite set S of sentences from a language (for which there is a compositional semantic theory), but that PB has learned the meanings of these sentences by dipping into a phrase book. Let us stipulate that PB treats each sentence in S as an unstructured string of letters or sounds, the meaning of which he needs to memorize. Consequently, PB has a separate piece of tacit or explicit knowledge about the meaning of each sentence in the set. We can say that PB has tacit or explicit knowledge of a noncompositional semantic theory with an axiom for each sentence in S. But PB's tacit or explicit knowledge about meanings is not adequate for understanding any sentence beyond the set S.

A semantic theorist could fit a compositional semantic theory to the sentences in S and extrapolate to sentences outside that set. But it is plausible that sentences outside S do not belong to the phrase-book 'language' that PB has learned, and that sentences outside S have no determinate meaning for PB – no determinate meaning in PB's language. Consequently, the appeal to tacit knowledge is to be preferred over the appeal to extrapolation (Schiffer, 1993, 2006). As Loar (1981) says, "the Chomskyan idea of the internalization of the generative procedures of a grammar has got to be invoked to…make sense of literal meaning."

Near the beginning of this article (Section Chomsky on the Faculty of Language), we noted that the notion of tacit knowledge does not figure in Chomsky's recent descriptions of his project (Chomsky, 2000, 2005; Hauser et al., 2002). Chomsky's account of the attained state of the faculty of language does not absolutely exclude the possibility that the subject has tacit knowledge of linguistic rules or principles – perhaps, tacit knowledge of a compositional semantic theory for her own language – embodied in some component of the mind/brain other than the faculty of language. But it is a significant question for future research whether appeal to a generative procedure can do the same work in philosophy

of language as the appeal to tacit knowledge of a compositional semantic theory.

A more general question in the same area is whether Chomsky's distinction between competence and performance can be retained if the attained state of the faculty of language is not to be conceived as a body of knowledge. Collins (2007) argues that the distinction does not depend on an epistemological – or even on a representational – understanding of competence. Linguistic cognition – and thence, linguistic behavior – depends on many component systems of the mind/brain. As Hauser et al. (2002) say, "a neuroscientist might ask: What components of the human nervous system are recruited in the use of language in its broadest sense? Because any aspect of cognition appears to be, at least in principle, accessible to language, the broadest answer to this question is, probably, 'most of it'…this conception is too broad to be of much use." Thus, reflecting normal scientific practice, the study of the faculty of language focuses on one component of the mind/brain "under idealization of its integration with other systems." The notion of competence "is intended to abstract one system [the faculty of language] out of an ensemble of systems whose integration underlies performance" (Collins, 2007).

Tacit Knowledge and Concept Possession

The notion of tacit knowledge also figures in philosophical theories about possession of concepts. One possible proposal in this area would be that possession of some concepts – particularly, concepts of logical operations such as conjunction and disjunction, but not only those – consists in tacit knowledge of logical or proper rules of inference that codify the inferential potential that is lodged in those concepts. Another possible proposal would be that possession of some concepts consists in tacit knowledge of definitions of those concepts.

Peacocke (2008) calls a state of tacit knowledge that is required for possession of a concept an 'implicit conception' and he proposes that, at least in some cases, an implicit conception is or includes a state of tacit knowledge of the contribution to truth conditions that is made by the concept. For example, in the case of the logical concept of (inclusive) disjunction, expressed by 'or,' this would not be tacit knowledge of rules of inference, but tacit knowledge that any proposition (thought content) of the form '*A or B*' is true if and only if either *A* is true or *B* is true. Such a state of tacit knowledge makes a common contribution to the explanations of the subject's evaluation for truth of many specific thought contents involving the concept (in the case of the example, a common contribution to the subject's truth-evaluation of many specific contents of the '*A or B*' form). The state of tacit knowledge of truth conditions can also contribute to the explanation of the subject's assessment of a principle or rule of inference as being valid or invalid. This proposal helps to explain the fact that even a primitive (nonderived) principle or rule of inference for a concept is susceptible of rational justification, a kind of justification that draws on the subject's grasp of the concept in question.

Here it is important to distinguish between two conditions that a principle might meet. First, it might be that personal-level acceptance of the principle can be justified by drawing on one's grasp of a particular concept. Second, it might be that personal-level acceptance of the principle is necessary for possession of the concept. Many principles that meet the first condition do not meet the second condition. In fact, some philosophers doubt that there are any principles at all that meet the second condition (Williamson, 2006). Suppose, though, that we were to allow (as conceptual-role theories of concept possession maintain) that, for a given concept, there are principles or rules of inference that do meet the second condition. That is, personal-level acceptance of, or commitment to, those principles or rules is necessary for possession of the concept. Peacocke (2008) argues that this could not provide a complete account of concept possession.

His argument appeals to "the phenomenon of new principles." There can be a principle involving a particular concept, which has two properties. First, the principle meets the first condition in the previous paragraph; that is, a subject can rationally justify acceptance of the principle by drawing on his grasp of the concept. Second, the principle is new, in the sense that it does not follow from the principles or rules already mentioned in the putative conceptual-role account of possession of the concept. These properties are together problematic for the conceptual role account because, according to that account, possession of the concept consists in personal-level acceptance of or commitment to principles or rules from which the new principle does not follow.

Rational justification of new principles has a ready explanation, however, if concept possession consists (in whole or in part) in tacit knowledge of the concept's contribution to truth conditions. Peacocke (2008) draws a parallel between explaining rational justification of new principles and explaining understanding of new sentences: "I am inclined to think that the Phenomenon of New Principles is as decisive an argument against personal-level conceptual role theories as the phenomenon of understanding sentences one has never encountered before is decisive against theories of meaning which do not proceed compositionally."

Implicit Rules in Connectionist Networks

A third point at which the notion of tacit knowledge figures in philosophical theory concerns the information processing that takes place in connectionist networks. A network consists of units, organized in layers, and weighted connections between units in successive layers. Input and output representations are patterns of activation across units in the input and output layers, respectively. Processing in a network is a matter of activation being passed from the input units to the output units, usually via a layer of hidden (i.e., neither input nor output) units. The activation of units in each successive layer is determined by the activation of units in the previous layer and the weights on the connections between the two layers. Thus, the precise weights on the connections are crucial for the network's performance of its task (e.g., generating an output representation of the correct pronunciation, given an input representation of a letter string). In this sense, a network's 'knowledge' about its task domain is embodied in the weights on its connections.

In a pioneering contribution to the development of connectionist models of cognitive processes, McClelland et al. (1986) highlighted a difference between connectionist models and earlier models by suggesting that connectionist networks "may provide a mechanism sufficient to capture lawful behavior, without requiring the postulation of explicit but inaccessible rules." In another influential paper, Rumelhart and McClelland (1986) said, "Using knowledge in processing is no longer a matter of finding the relevant information in memory and bringing it to bear; it is part and parcel of the processing itself." These (and many similar) passages draw attention to significant features of connectionist networks. But it is important to see that they do not, by themselves, reveal a difference between processing in networks and processing that is guided by tacitly known rules.

Earlier (Section Rule-Explicit and Rule-Implicit Systems), we distinguished between rule-explicit and rule-implicit systems. Tacit knowledge of a rule may involve explicit storage: a representation that encodes the rule must be searched for and accessed before the tacit knowledge can be used. We also noted earlier that explicit storage is not sufficient for explicit knowledge. Tacit knowledge of rules may involve explicit storage of information that is not available to the subject for verbal report and not accessible to the subject's consciousness. This kind of tacit knowledge ('finding the relevant information in memory and bringing it to bear'; 'explicit but inaccessible rules') can, indeed, be contrasted with the way in which knowledge about a task domain is embodied in a connectionist network.

But a rule may be both tacitly known and 'wired in' to a system, because a component processor, no less than an explicitly stored representation, can make a common contribution to the content-involving explanations of many transitions between representations. Peacocke (2008) makes the same point about implicit conceptions. At the subpersonal level, the content of an implicit conception might be 'explicitly formulated in a language of thought' or 'grounded in the operation of a processor.' When a tacitly known rule is implicit or 'wired in,' it is well described as 'part and parcel of the processing.' Thus, the connectionist architecture of units and activations, connections and weights, does not exclude the possibility that tacit knowledge of rules may be embodied in networks.

If we consider again the very simple example of transitions from representations of three-letter strings to representations of their pronunciations, it is certainly possible to describe a connectionist network in which tacit knowledge of each of the 15 letter–sound rules is embodied in a particular set of weighted connections, so that the causal-explanatory structure is like that in Syst. And it is possible to describe a different network in which tacit knowledge of each of the 125 one-case pronunciation rules is embodied in a particular set of weighted connections, so that the causal-explanatory structure is like that in List (Davies, 1995). With more realistic tasks (e.g., when a proportion of the letter strings have irregular or exception pronunciations), and with networks that are more typical of contemporary connectionist research (e.g., Plaut et al., 1996), it is usually not possible to identify component processors (sets of weighted connections) that embody letter–sound rules. Nevertheless, it may be possible to find theoretically significant commonalities in the processing of similar items, and the pattern of commonalities may be preserved across different networks (e.g., with different numbers of units and connections) that perform the same task (Shea, 2007).

Tacit Theory and Simulation in Everyday Psychological Understanding

A fourth example is provided by the debate between the theory theory and mental simulation approaches to everyday psychological understanding (Davies and Stone, 1995). On both sides of the debate, it is agreed that we have a capacity to predict, interpret, and explain the mental lives of other people. What is the basis of this capacity? According to the theory theory, we draw on a rich body of knowledge about psychological matters – a theory, in a suitably inclusive use of that term. According to the simulation theory, in apparent contrast, we identify with the other person in imagination and replicate or reenact aspects of the other person's mental life. If the other person is thinking about interest rates and the stock market, then we think about those same financial matters (we 'co-cognize' with the other person) rather than drawing on a rich body of psychological principles concerned with how people think about financial matters (Heal, 1986, 1998).

The theory theory faces objections if its claim is that ordinary people with a normal capacity for everyday psychological understanding have a rich body of explicit knowledge about psychological matters. Ordinary people are generally not able to articulate many principles of psychological theory: "[W]hy, one wonders, should it be so difficult to articulate laws if we appeal to them all the time in our interpretive practice?" (Goldman, 1989). The obvious response on behalf of the theory theory is to say that the rich body of knowledge is tacit knowledge rather than explicit knowledge. Thus, Stich and Nichols (1992) draw attention to the 'dominant explanatory strategy' in cognitive science, which is to appeal to "an internally represented 'knowledge structure'…which serves to guide the execution of the capacity to be explained." On their account, the theory theory says that everyday psychological understanding is explained by the presence of a 'largely tacit psychological theory.'

A concern about the shape of the debate may then arise. The theory theory and the simulation theory were supposed to be competing accounts of the basis of our capacity for everyday psychological understanding. But, depending on what it takes for a theory to be tacitly known, might not the simulation theory turn out to be consistent with – even a version of – the tacit theory theory? Blackburn (1992) gives expression to this concern that the tacit theory theory may be so undemanding as to subsume the supposed simulation alternative: "If we are good at something…then we can be thought of as making tacit (very tacit) use of some set of principles that could, in principle, provide a description of a device…that is also good at it."

The concern would be justified if tacit knowledge were to be conceived in the way that Blackburn envisages. The debate between the tacit theory theory and the mental simulation theory would collapse if the attribution of tacit knowledge of principles to a person with a particular capacity required no

more than that explicit knowledge of the principles should suffice for having the capacity, or no more than that behavioral manifestations of the capacity should conform to the principles, or no more than that it should be as if the person knew the principles.

The account of tacit knowledge given in this article (Section An Account of Tacit Knowledge) is certainly more demanding than those trivializing accounts. But Heal (1994) has argued that, even on that account of tacit knowledge, the mental simulation theory turns out to be a version of the tacit theory theory. In fact, she argues more generally that, if a mechanism is used to simulate the operation of other mechanisms of the same kind so as to permit predictions about them, then the mechanism used for simulation embodies tacit knowledge of theoretical principles about how mechanisms of that kind operate.

Suppose (to take an extremely simple example) that a subject, S, begins with the information about another person, O, that O believes the proposition that interest rates are falling (*p*). Suppose, too, that S wonders whether, if the question of the truth of the disjunctive proposition that interest rates are falling or the stock market is rising (*p or q*) arises, O will believe that it is true. In order to generate a prediction about O, S co-cognizes with O and, in suppositional or imaginative mode, thinks that *p* and considers whether the proposition *p or q* is true. Drawing on her own tacit knowledge of the inference rule of '*or*'-introduction or her own tacit knowledge of the contribution made to truth conditions by the concept of (inclusive) disjunction, S concludes that *p or q* is true. Then, on the basis of this simulation exercise, S predicts that O will believe *p or q*.

Clearly, S could proceed in the same way in a multitude of actual or potential cases. Beginning from the information that a subject X believes a proposition *A*, S would arrive at the prediction that X will believe a proposition of the '*A or B*' form if the question of that proposition's truth arises. Furthermore, S's transition would have the same causal explanation in each case. Thus, Heal (1994) argues, S has tacit knowledge of the general psychological principle that if X believes *A* then X will also believe *A or B* – just as the tacit theory theory would say.

Davies and Stone (2001) respond to Heal's argument with two points. First, the attribution to S of tacit knowledge of the psychological principle that if X believes *A* then X will also believe *A or B* is unmotivated. Simulation theorists, including Heal, agree that the use of mental simulation to arrive at psychological predictions about other people depends on tacit or explicit knowledge or acceptance of some principle linking the simulating subject's own thinking with other people's thinking. One example of a principle of this kind is (Sim–Other): If, within the scope of a simulation exercise that begins from the thought *C*, I arrive at the thought *D* then, if O believes *C* then *ceteris paribus* O will also believe *D*. The transition in S's simulation exercise from the thought that interest rates are falling (*p*) to the thought that interest rates are falling or the stock market is rising (*p or q*), together with S's acceptance of the principle (Sim–Other), already provides an explanation of S's proceeding from the information that O believes *p* to the prediction that O will believe *p or q*. No additional knowledge, tacit or explicit, about psychological matters is required.

The second point that Davies and Stone (2001) make is that the attribution to S of tacit knowledge of the psychological principle that if X believes *A* then X will also believe *A or B* is not licensed by the account of tacit knowledge. Heal allows that some component of S's subpersonal-level reasoning system embodies tacit knowledge about the inferential or truth-conditional properties of disjunction and she proposes that this same information-processing component also embodies tacit knowledge of the principle that if X believes *A*, then X will also believe *A or B*. But states of tacit knowledge figure in content-involving explanations and the component in question does not play the right causal-explanatory role to embody tacit knowledge of that principle. A state of tacit knowledge of the psychological principle would explain transitions between representations under their content-involving descriptions. These would have to be representations with contents of the forms 'X believes *A*' and 'X believes *A or B*.' But the information-processing component in question mediates transitions between states whose contents do not concern believing at all but instead (in our example) concern financial matters. The transition between representations with contents 'interest rates are falling' and 'interest rates are falling or the stock market is rising' is, of course, entirely appropriate to the causal-explanatory role of a state of tacit knowledge about the inferential or truth-conditional properties of disjunction. But it is not appropriate to the causal-explanatory role of a state of tacit knowledge of a psychological principle.

Tacit Knowledge in Psychology: The AGL Task

Half a century ago, Chomsky's notion of tacit knowledge of the rules of a generative grammar provided the theoretical background for empirical research on artificial grammar learning (AGL). Chomsky's early work on formal language theory also provided the main tool that has been used in this research.

In a typical AGL experiment, the grammar in question is a regular or finite state grammar. Chomsky (1956) described finite state grammars, phrase structure grammars, and transformational grammars, and showed that finite state grammars cannot capture the syntax of English. Chomsky and Miller (1958) provided a more extensive formal account of finite state grammars and the languages that they generate. Although finite state grammars do not include a grammar for English, they illustrate well enough the core notions that Chomsky associates with the faculty of language: a finite vocabulary and a procedure that generates infinitely many finite complex structures (expressions) from the vocabulary items.

Finite State Grammars

A finite state grammar can be represented graphically by a state diagram (a diagram for a finite state automaton); an example is provided in **Figure 1**. There is a finite set of states – in the example, four states (S_1, S_2, S_3, S_4) apart from the start and end states (S_0 and $S_{0'}$); and arrows indicate possible transitions between states. The vocabulary is a finite set of items – in the example, the set of letters {P, S, T, V, X}. Beginning in the start state, S_0, each successive transition adds

a letter to the string. The state that the system is in fully determines which letters can be added to the string (e.g., in state S_2, S or X can be added). No memory for earlier transitions, or for letters already in the string, is required.

A string of letters is an expression of the language generated by the grammar just in case it corresponds to a path through the state diagram, from the start state to the end state. Thus, the strings TTS and VVS are expressions of the language generated by the grammar corresponding to the state diagram in Figure 1, as are TPTS, TPPTS, TPPPTS, and so on, and TTXVPS, TTXVPXVPS, TTXVPXVPXVPS, and so on.

A grammar is canonically specified by a set of rules and the rules of a finite state grammar have the form: A → *a* B, where A denotes a state other than the end state, *a* denotes a vocabulary item, and B denotes a state. The rules of a finite state grammar correspond to the possible transitions in the state diagram that represents the grammar graphically. Each rule specifies the state in which the transition applies, the vocabulary item that is added to the string, and the state following the transition. Thus, the rules of the grammar represented by the state diagram in Figure 1 include: $S_0 \rightarrow T\,S_1$, $S_0 \rightarrow V\,S_3$, $S_1 \rightarrow P\,S_1$, $S_1 \rightarrow T\,S_2$, $S_2 \rightarrow X\,S_3$, $S_2 \rightarrow S\,S_{0'}$ and so on. The rules can be read as saying that the symbol on the left of the arrow can be replaced by the symbols on the right (they are 'rewrite' rules). A string, *w*, is said to be generated by the grammar if and only if it is possible to begin with the symbol for the start state and reach *w* (followed by the symbol for the end state) by a finite sequence of rule applications. Thus, for example, a derivation of the string TTS would proceed from S_0 to $T\,S_1$ (by the first rule above), then to $TT\,S_2$ (by the fourth rule), and finally to $TTS\,S_{0'}$ (by the sixth rule). For the purpose of displaying the derivations of strings, a more perspicuous notation would use the null symbol to denote the end state. Rules would have the form A → *a* B (as before) or A → *a*, and the sixth rule would be simply $S_2 \rightarrow S$.

Learning and Classification

In a typical AGL experiment, subjects learn to classify letter strings as being grammatical or ungrammatical. In general, there are many ways in which subjects may learn to classify items as belonging or not belonging to some category. In one kind of case, subjects may be provided with a principle or rule of classification. That is, a teacher may make a rule explicit and the subjects may acquire explicit knowledge of the rule and use that explicit knowledge in making their classifications.

Figure 1 Diagram of a finite state grammar.

In other cases, subjects may simply be provided with a set of exemplars of the category to study or memorize. After a period of exposure to the exemplars, subjects may achieve performance on the classification task that is significantly better than would be predicted if they were guessing (or tossing a coin). In principle, their classifications might even be reliably correct. A subject who has attained this level of performance may also be able to state a rule to which his or her classification performance reliably conforms. That is, even without being explicitly told any rule of classification, the subject may acquire explicit knowledge of a rule. In such a case, it may be (though it need not be) that it is because the subject has acquired explicit knowledge of the rule that his or her classifications are reliably correct.

It may, however, happen that, following the period of exposure to exemplars, the subject achieves classification performance that substantially, or even reliably, conforms to a rule of classification, although the subject is quite unable to state the rule. Indeed, the subject may be unable to provide any illuminating account of how he or she is making the classification. Such a case fits Polanyi's (1967) conception of tacit knowing – knowing more than one can tell. The subject is able to – has learned to – make the classification, but cannot tell – cannot make explicit – how to make the classification.

Cases of this kind are sometimes described as examples of implicit learning: the subject "learns about the structure of a fairly complex stimulus environment, without necessarily intending to do so, and in such a way that the resulting knowledge is difficult to express" (Dienes and Berry, 1997). Implicit learning is an unconscious and unintentional process (Shanks, 2005) – in contrast to learning by testing or evaluating explicitly formulated hypotheses, for example. Because the description of implicit learning seems to fit learning (or, more generally, acquisition) of our first language, it is natural to ask whether implicit learning results in Chomskyan tacit knowledge of a rule (or a set of rules) of classification.

Implicit Learning and Tacit Knowledge of Rules

At the beginning of a seminal paper in which the term 'implicit learning' was introduced, Reber (1967) wrote: "In recent years, the model of the verbal organism as an imitative and generalizing mechanism has been largely replaced by a model that characterizes him as a 'sentence generating machine' who has learned a 'generative grammar' in some implicit fashion." In the learning phase of his first AGL study, Reber (1967, Experiment 2) presented subjects with 20 strings generated by the finite state grammar in Figure 1. In this phase, there was no mention of grammars or rules and the subjects were required simply to memorize the presented strings. At the beginning of the test phase of the study, subjects were told that the 20 strings had been generated by a set of grammatical rules, but they were provided with no further information about the rules. Subjects were then asked to classify new strings as either grammatical or ungrammatical. Each new string was presented twice and the striking finding was that 79% of the subjects' classification responses were correct (with 69% of the new strings classified correctly on both presentations).

A separate experiment (1967, Experiment 1) showed that, following an extensive learning phase (in which, again, there

was no mention of grammars or rules), subjects were unable to answer any questions about what the rules governing the strings might be. Unless they were given considerable prompting, subjects were unable even to say which letters the strings could begin with (T or V) or end with (only S). Reber concluded that the learning phase of the experiment provided subjects with abstract information about the rule-governed structure of the presented strings; and that this information was used to classify new strings in the test phase, although no verbal account of the rules could be elicited from subjects. In short, Reber's view was that, through a process of implicit learning, tacit knowledge of rules was acquired.

Skepticism about Implicit Learning

It has been argued, however, that it would be possible for subjects to achieve the better-than-chance classification performance that is typically demonstrated in the test phase of an AGL experiment without acquiring knowledge of the rules of the grammar used to generate the strings presented in the learning phase. One proposal is that information about pairs of adjacent letters (bigrams) that occur in the presented strings (perhaps along with information about allowable first and last letters) would be sufficient to account for subjects' classification performance. Furthermore, the results of a recognition memory test support the hypothesis that, in the learning phase, subjects acquire explicit knowledge about which bigrams occurred in the presented strings. Thus, an alternative to Reber's view is that what is acquired during the learning phase and used during the test phase is not tacit knowledge of abstract rules but explicit knowledge of specific fragments (Perruchet and Pacteau, 1990). In a review of research on implicit learning, Shanks (2005) supports this alternative proposal: "participants merely focus on and learn about small letter chunks. In the test stage they endorse (i.e., call grammatical) any item composed mainly of familiar letter pairs."

Here it is relevant that there are findings of transfer of classification performance to strings that are generated by the same finite state grammar, but from a new set of letters (Reber, 1969), or even to strings of stimuli presented in a different modality from those in the learning phase (e.g., letters vs tones; Altmann et al., 1995). Reber explains transfer in terms of abstract knowledge (even if not knowledge of the basic rules of the grammar) acquired during the learning phase. An alternative proposal is that transfer can be explained in terms of abstraction or analogical reasoning in the test phase from explicit knowledge, about specific fragments (e.g., bigrams or trigrams) or about specific complete exemplars, acquired in the learning phase. Shanks (2005) argues that the balance of evidence favors the alternative proposal and concludes: "In a nutshell, performance in AGL experiments appears to be fully explained without the need to impute unconscious rule-learning."

AGL in Patients with Amnesia

In comparing Reber's view with alternatives, we have contrasted implicit abstract knowledge with explicit specific knowledge. But the implicit versus explicit distinction and the abstract versus specific distinction are not to be conflated.

Patients suffering from amnesia cannot (by definition) retain new explicit knowledge but, in AGL experiments, they show very similar classification performance to that of age-matched controls (Knowlton and Squire, 1994, 1996). This finding is enough to rebut any suggestion that acquisition of explicit knowledge in the learning phase is essential for better-than-chance classification performance in the test phase of AGL experiments. But the fact that patients with amnesia cannot rely on explicit knowledge acquired in the learning phase to classify new strings presented in the test phase does not settle the question whether the patients rely on abstract or specific information or both.

Knowlton and Squire showed that, in both patients and controls, classification performance was influenced by the occurrence in test strings of bigrams and trigrams (chunks) that occurred frequently in strings presented in the learning phase, despite the fact that the patients with amnesia scored only marginally above chance on a recognition memory test for chunks that had appeared in the learning phase. Classification performance was also influenced by whether the test strings conformed to the rules of the grammar and there was some transfer of performance to test strings composed from a new set of letters (though at a lower level than with test strings composed from the original set of letters). At least in the case of patients with amnesia, it is not plausible that transfer of classification performance depends on abstraction or analogy in the test phase, based on explicit knowledge about chunks or complete strings retained from the learning phase. Rather, it seems that patients acquire specific information about chunks and complete strings presented in the learning phase, and also more abstract information that supports transfer.

Knowlton and Squire's (1994, 1996) findings do not exclude the possibility that subjects with unimpaired memory – and particularly, perhaps, healthy younger subjects – may acquire in the learning phase, and use in the test phase, information that is available for verbal report. But the findings, and the similar performance of patients and age-matched controls, certainly suggest that, even if in normal healthy subjects some of the relevant information is available for verbal report, not all of it is. As Reber (1989) puts the point: "The implicitly acquired epistemic contents of mind are always richer and more sophisticated than what can be explicated."

Conscious and Unconscious Knowledge

It will be clear from the previous section that the dialectical context of AGL experiments is different from that of typical appeals to tacit knowledge in philosophy. Philosophical appeals to tacit knowledge typically occur in contexts where it is not in dispute that relevant explicit knowledge is lacking. In AGL research, in contrast, the claim that what has been acquired in the learning phase is implicit or tacit knowledge, rather than explicit knowledge, is highly contested. It is also a feature of AGL research that the question of what has been acquired in the learning phase is often formulated in terms of conscious knowledge versus unconscious knowledge – a contemporary version of the explicit knowledge versus implicit knowledge contrast. Thus, considerable importance

attaches to the empirical assessment of conscious versus unconscious knowledge.

Two Criteria for a Test of Conscious Knowledge

Shanks and St John (1994) argue that, in studies that aim to demonstrate that unconscious knowledge (e.g., Chomskyan tacit knowledge of rules) has been acquired through implicit learning, two criteria must be met in order to exclude the possibility that what subjects have acquired is really conscious knowledge. First, if the subjects' awareness of a particular kind of information is tested, then this must be the same kind of information that is drawn on in the subjects' performance: the information criterion. For example, in Reber's (1967) study, subjects' conscious knowledge of the rules governing the presented strings was tested. So it is important that it should be information about those rules that was drawn on in subjects' classification of new strings as grammatical or ungrammatical. Clearly, no tacit knowledge or implicit learning is demonstrated if one kind of information (e.g., about bigrams that occurred in strings presented in the learning phase) is drawn on in subjects' performance but subjects are found to be unaware of some other kind of information (e.g., about the rules of the finite state grammar).

The second criterion is that tests of subjects' conscious knowledge should be sufficiently sensitive to reveal all of the relevant conscious knowledge: the sensitivity criterion. Here it is relevant that, in research on memory, both recall and recognition have been regarded as explicit tests of memory (Schacter, 1989), with recognition being generally more sensitive than recall. Thus, if subjects' performance on a classification test were to draw on information about grammatical rules, then simply asking subjects what the rules are (a test of free recall) would meet the information criterion, but might be relatively insensitive to subjects' actual conscious knowledge of rules. For example, subjects might not volunteer a statement of conscious knowledge about which they were not confident. If a test of conscious knowledge used in an AGL experiment does not meet both the information criterion and the sensitivity criterion then task-relevant conscious knowledge acquired during the learning phase may be underestimated – and implicit learning may be correspondingly overestimated.

Exhaustiveness and Exclusiveness

Lessons for research on implicit learning have also been drawn from Reingold and Merikle's (1990) discussion of research on unconscious perception. They note that one requirement for an adequate measure of conscious awareness is that it should be exhaustive (a requirement very similar to the sensitivity criterion). Given a finding that performance apparently outruns conscious perception (in Reingold and Merikle's case) or conscious knowledge (in the AGL case), it cannot be concluded that there is perception or learning without awareness if the test of conscious awareness is not exhaustive.

A second requirement for a test of conscious awareness is that it should be exclusive; that is, results on the test should be influenced only by conscious, and not also by unconscious, perception or knowledge. Given a finding that performance apparently does not outrun conscious perception or knowledge, it cannot be concluded that there is no perception or learning without awareness if the test of conscious awareness is not exclusive (Reingold and Merikle, 1990). In the AGL case, specifically, results on a test of conscious awareness of what has been learned should be influenced only by conscious knowledge, and not contaminated by unconscious knowledge.

As Shanks and St John (1994) in effect pointed out, if a test of conscious knowledge is not exhaustive then it may underestimate conscious knowledge and overestimate implicit learning. Now we should add that if a test is not exclusive, then it may overestimate conscious knowledge and underestimate implicit learning. Different theorists put more stress on the exhaustiveness (sensitivity) requirement or on the exclusiveness requirement and this may reflect, in part, their view as to whether conscious or unconscious processing enjoys theoretical primacy. One influential view is that, in human beings, conscious learning is the default case and 'unconscious learning has not yet been satisfactorily established' (Shanks and St John, 1994; see also Shanks, 2005). Reber, on the other hand, defends the primacy of the implicit (Reber, 1990).

Validating a Test of Conscious Knowledge

Unless a test of conscious knowledge is, and is known to be, both exhaustive and exclusive, it cannot, by itself, be used to adjudicate evenhandedly a putative case of implicit learning. We have already seen that a test of conscious knowledge based on free recall is unlikely to be exhaustive. Tests based on recognition memory (rather than recall), which we have mentioned as being more sensitive to conscious knowledge, may not be exclusive because responses may be contaminated by unconscious processes. For example, recognition judgments are influenced by perceptual fluency. Subjects are more likely to 'recognize' a test word falsely as having occurred on a previously studied list if their perception of the test word is facilitated by very brief prior presentation of the same word under conditions (masking) that preclude conscious perception (Jacoby and Whitehouse, 1989).

The fact that a recognition memory test of conscious knowledge is not exclusive illustrates the more general point that distinctions between psychological tasks (e.g., between the so-called explicit and implicit tests of memory) do not coincide with distinctions between psychological processes (Jacoby, 1991). Recognition has been regarded as an explicit test of memory, but the results of a recognition test may be influenced by unconscious, as well as by conscious, processes. More generally, we should not assume that an experimental task (particularly, a task used as a test of conscious knowledge) is 'process pure,' that is, that it involves only conscious processes or else only unconscious processes. There is no a priori guarantee that any particular test of conscious knowledge will be exhaustive and exclusive.

Reingold and Merikle (1990) argue for an approach on which a putative test (or 'operational definition') of conscious awareness is validated by converging empirical evidence. In their view, the theoretical importance of the distinction between conscious and unconscious processes lies in the existence of qualitative differences between the two. Sometimes, indeed, conscious and unconscious processes are not just qualitatively different, but opposed to each other. For example, the

recognition memory experiment briefly mentioned two paragraphs back involved two conditions. In one (unaware condition, described above), presentation of a test word was preceded by a very brief masked presentation of the same word. In the aware condition, in contrast, presentation of a test word was preceded by a presentation of the same word that was long enough to allow conscious perception. As described above, subjects in the unaware condition were more likely to 'recognize' the test word falsely as having occurred on a previously studied list (by comparison with an appropriate baseline condition in which there was no prior presentation of the test word). But subjects in the aware condition were less likely (than in the baseline condition) to 'recognize' the test word falsely as having occurred on the previously studied list.

Thus, there is the prospect that a putative test of conscious knowledge can be validated in the context of psychological theory to the extent that the test correctly predicts processing of qualitatively different – perhaps opposed – kinds. In the next section, we describe some AGL research that adopts the approach recommended by Reingold and Merikle.

Conscious Knowledge in the Context of Psychological Theory

In the learning phase of an AGL experiment, subjects may acquire knowledge about the structure of the presented strings. This may be knowledge of rules or knowledge about individual strings. Possible examples of knowledge of rules include not only knowledge of the rules of the finite state grammar that was used to generate the strings, but also knowledge of simpler rules such as that strings can begin with T or V, that all strings end with S, and that P can be repeated. Possible examples of knowledge about individual strings presented in the learning phase include knowledge that the string VXXVS was presented, that a string including the bigram TS was presented, and that a string including the trigram VPX was presented. (The distinction between the two kinds of knowledge is not sharp. If a string beginning with VX was presented in the learning phase, then strings can begin with VX.) The knowledge acquired in the learning phase may be drawn on in the test phase as subjects make judgments about test strings – judgments that the strings are grammatical (that is, conform to the rules that were used to generate the strings presented in the learning phase) or ungrammatical.

Conscious and Unconscious Judgment Knowledge

Dienes and Scott (2005) distinguish between structural knowledge acquired during the learning phase and what they call 'judgment knowledge' arrived at and deployed in the test phase – for example, the knowledge that the string VVPXXVS, presented in the test phase, is grammatical. The aim of their study was to assess knowledge as conscious or unconscious, in the context of psychological theories about conscious and unconscious processes.

Dienes and Scott commend two confidence criteria for unconscious knowledge, the guessing criterion and the zero-correlation criterion (see also Dienes, 2008, 2012). A subject who is asked to judge whether strings of letters are grammatical or not may, on some trials, believe him- or herself to have no basis for the judgment and, consequently, he or she may have no confidence in his or her judgment; he or she may describe him- or herself as guessing. (Strictly speaking, he or she may have confidence of 50% in his or her judgment – he or she might as well be tossing a coin.) If the subject's guessing responses are correct at a rate that is better than chance, then this is evidence (that is, prima facie but defeasible evidence) of unconscious judgment knowledge (according to the guessing criterion).

On other trials, the subject may believe him- or herself to be knowledgeable to some extent and may have some degree of confidence in his or her judgment. If the subject's guessing responses and these more confident responses together reveal a correlation between accuracy and confidence, then this is evidence of some conscious judgment knowledge. If there is no correlation between accuracy and confidence but the subject's overall performance is better than chance then this is, again, evidence of unconscious judgment knowledge (according to the zero-correlation criterion).

Clearly, the use of the guessing criterion and the zero-correlation criterion may provide evidence of both unconscious and conscious judgment knowledge. For example, a subject's guessing performance may be better than chance and his or her more confident judgments may be more likely to be correct than his or her guesses. Dienes and Scott (2005) investigated judgment knowledge by asking subjects in the test phase of an AGL experiment to classify each string as grammatical or ungrammatical and then to indicate their degree of confidence in the classification judgment (from 50 to 100% confident). Overall, subjects' confidence ratings provided evidence of both unconscious and conscious judgment knowledge.

Conscious and Unconscious Structural Knowledge

In principle, it would seem that conscious or unconscious judgment knowledge and structural knowledge could be combined in three ways. In the case of guessing, there is no conscious judgment knowledge or conscious structural knowledge. But conscious judgment knowledge can be combined with either unconscious or conscious structural knowledge. When a subject's judgment knowledge is conscious but his or her structural knowledge is unconscious, the phenomenology may be that of intuition.

Dienes and Scott (2005) investigated structural knowledge by asking subjects to indicate the source of their judgment knowledge, choosing between four options: guess (it seemed to the subject that the judgment had no basis whatsoever); intuition (the subject had some confidence in the judgment but had no idea why it was right); rules (the subject felt that he or she based the judgment on some rule or rules acquired in the learning phase – rules that he or she could state if asked); and memory (the subject felt that he or she based the judgment on memory for particular items or parts of items from the learning phase). The 'guess' and 'intuition' responses provided evidence that the subject's structural knowledge was unconscious, while the 'rules' and 'memory' responses provided evidence that it was at least partly conscious. Some more recent studies include an additional potential source of

subjects' judgment knowledge: familiarity (the subject felt that he or she based the judgment on a feeling of familiarity but had no idea what the familiarity itself was based on). The 'familiarity' response, like the 'intuition' response, provides evidence of unconscious structural knowledge (Scott and Dienes, 2008; see Dienes et al., 2011, for a review).

It is independently plausible on theoretical grounds that the acquisition and use of conscious structural knowledge would make demands on working memory and executive function. Thus, having subjects perform an executive working memory load task (e.g., generating random numbers) during the learning phase of an AGL experiment should disrupt the acquisition of conscious structural knowledge by comparison with unconscious structural knowledge. If 'rules'/'memory' responses indicate conscious structural knowledge, then one can predict that subjects who performed a load task during the learning phase should be less likely (than subjects who did not perform the load task) to attribute the source of their judgments in the test phase to rules or memory. This prediction was confirmed in Dienes and Scott's (2005) study and, to that extent, the use of the 'rules'/'memory' versus 'guess'/'intuition' contrast to distinguish between conscious and unconscious structural knowledge was validated.

The study by Dienes and Scott (2005) investigated the distinction between conscious and unconscious structural knowledge in the context of psychological theory about working memory and executive function. But the load task manipulation did nothing to validate the distinction between conscious and unconscious judgment knowledge.

The Serial Reaction Time Task

Converging evidence to support the distinction between conscious and unconscious judgment knowledge has come from a different implicit learning paradigm, the serial reaction time (SRT) task (Destrebecqz and Cleeremans, 2001). In the learning phase, subjects see a sequence of stimuli on a computer screen. Each stimulus appears at one of several (e.g., four) possible locations on the screen and the subject's task is simply to press a key corresponding to the stimulus location as quickly as possible. In fact, the sequence of stimuli follows a repeating pattern, in which the locations are determined by second-order conditional rules. That is, each position is determined by the previous two positions (e.g., positions 4 and then 2 are always followed by position 3). Learning is revealed in the pattern of reaction times, which decrease as the learning phase progresses, increase sharply when a new sequence is introduced, and then drop back to the lower level when the original sequence returns.

In the test phase, there are two conditions, motivated by Jacoby's (1991) 'process dissociation framework.' The leading idea is that the use of conscious knowledge can be controlled, whereas the use of unconscious knowledge is automatic. In one condition of the test phase (inclusion), subjects are asked to generate a sequence that resembles the training sequence as much as possible. In this condition, automatic use of unconscious knowledge is facilitatory. Subjects can perform the task by drawing on either conscious or unconscious knowledge about which position would be a legal continuation of the sequence (e.g., that 3 would be a legal continuation of …42). Consequently, legal continuations in the inclusion condition do not provide evidence that distinguishes between conscious and unconscious knowledge acquired during the learning phase.

In a second – theoretically crucial – condition (exclusion), subjects are asked to generate a sequence that avoids the regularities of the training sequence. In this condition, controlled use of conscious knowledge and automatic use of unconscious knowledge are set against each other. To perform the task, subjects need to make controlled use of their conscious knowledge about which position would be a legal continuation. Specifically, they need to continue in a way that avoids that position. In this condition, automatic use of unconscious knowledge interferes with, rather than facilitates, performance of the exclusion task. Thus, legal continuations in the exclusion condition provide evidence of unconscious knowledge acquired during the learning phase. (Relevant evidence would include the proportion of legal continuations being above a suitable baseline and there being no fewer legal continuations in the exclusion than in the inclusion condition.)

The results of experiments using the SRT task do not all point in the same direction. But, given appropriate conditions in the learning phase, evidence from the exclusion condition in the test phase does support the hypothesis that unconscious knowledge about legal continuations is acquired (Destrebecqz and Cleeremans, 2001; Fu et al., 2008). Furthermore, it can be argued that the relevant distinction for the application of Jacoby's (1991) process dissociation framework to sequence generation in the test phase of the SRT task is not between conscious and unconscious structural knowledge, but between conscious and unconscious judgment knowledge. Specifically, the relevant distinction is between intuition and guessing, because conscious judgment knowledge that is based on unconscious structural knowledge can still be controlled (Fu et al., 2010).

Summary and Continuing Research

When the distinction between explicit and implicit knowledge is interpreted as that between conscious and unconscious knowledge, empirical research using the AGL task can be seen as a chapter in the scientific study of consciousness. In this research, attributions of tacit knowledge of rules, and of unconscious knowledge more generally, have been contested and various requirements for a test of conscious knowledge have been proposed.

There is no test of conscious knowledge for which we have a guarantee that it will meet the demanding requirements of exhaustiveness and exclusiveness – revealing all the relevant conscious knowledge while remaining uncontaminated by unconscious knowledge. But putative tests may be validated by converging evidence in the context of psychological theory. Dienes and colleagues have proposed tests for conscious judgment knowledge (based on subjects' confidence ratings) and conscious structural knowledge (based on subjects' source attributions for their judgments). As briefly described in the preceding section, they have taken steps to validate the tests by appeal to converging evidence from (respectively) the exclusion condition of an experiment based on Jacoby's

(1991) process dissociation framework and an executive working memory load task (see Dienes, 2012, for a review).

Recent and continuing research on implicit learning, using the AGL task, is investigating new measures of conscious awareness such as wagering (Persaud et al., 2007; Dienes and Seth, 2010), and comparing different measures (Wierzchoń et al., 2012). Research also continues on feelings of familiarity and their relationship to perceptual fluency (Scott and Dienes, 2008, 2010; Dienes et al., 2011) and the AGL paradigm has been adapted to investigate cross-cultural differences in unconscious processes (Kiyokawa et al., 2012). In other work, researchers have developed implemented computational models of implicit learning tasks, including the AGL and SRT tasks (see Cleeremans and Dienes, 2008, for a review).

Finally, the methods of AGL are being used, in conjunction with formal language theory, to investigate learning – particularly, implicit learning – of grammars with greater expressive power than regular (that is, finite state) grammars (Rohrmeier et al., 2012). (Recall that Chomsky (1956) showed that finite state grammars cannot capture the syntax of English.) Some of this research extends to AGL in preverbal infants and nonhuman animals and addresses the questions whether the human capacity to acquire supraregular grammars is biologically distinctive and what its neural substrate might be (Fitch et al., 2012; Fitch and Friederici, 2012).

Abstract

The geography of knowledge studies spatial variations in the generation, dissemination, and application of various categories of knowledge. Scholars in this area are interested in the places and spaces of knowledge generation and the impact of local milieus (environments) and spatial relations on the generation and diffusion of knowledge. They analyze the reasons for spatial disparities of knowledge and their consequences for society and economy.

Introduction

The geography of knowledge examines spatial variations in the generation, dissemination, and application of various categories of knowledge. Interest focuses on the spatiality of learning and problem solving and on the impact that places, spatial relations, local milieus, and political and socioeconomic structures have on the generation and dissemination of knowledge. Scholars analyze the reasons for spatial disparities of knowledge and their consequences for society and economy. Research focuses on relationships between knowledge and power, knowledge and competitiveness, knowledge and migration, the ethnic and cultural dimension of knowledge, and other issues related to spatial variations of knowledge. This article first discusses the spatiality of learning processes and some of the main reasons why spatial differences of knowledge are so persistent over time. It then turns to methodological issues of localizing knowledge, and introduces various categories of knowledge. In its main part it focuses on the process of communicating different categories of knowledge from A to B; coalitions between knowledge and power; the attractiveness of power centers for highly skilled professionals; and the distribution of knowledge-intensive jobs in the hierarchy of the urban system.

Spatiality of Knowledge

Spatiality of Learning Processes

Learning processes and problem solving do not take place in a social, political, or economic vacuum. They are influenced by a multitude of factors whose local interaction results in a spatial context, milieu, or environment. A knowledge environment, as a context of action, consists above all of knowledgeable actors capable of interacting with one another at a location. It is shaped also by infrastructure, resources, organizational structures, and rules, stimuli, informal expectations, and pressures influencing the activities and value systems of people. What counts is the 'local buzz' (Asheim et al., 2007; Bathelt et al., 2004; Storper and Venables, 2004), the intensity and quality of interaction among these elements at a given location and time period. In each domain (e.g., scientific disciplines, production of jewelry, financial services, software development, arts), talented individuals need specific knowledge milieus within which they can work on their creative ideas or follow their professional ambitions. Within each domain, knowledge environments at various locations differ from each other and build a ranking of attractiveness. Outstanding knowledge milieus are able to keep their high reputation only if they can attract the best available agents in their domain from elsewhere. The spatial mobility of scholars, highly educated professionals, creative artists, brilliant students, and distinguished top managers is therefore one of the core research questions in the geography of knowledge.

Knowledge cultures, learning and research conditions, spatial arrangements of infrastructure, and innovative milieus should not be conceived of as a variable determining the activities of people in a location and having predictable effects on all actors involved, but rather as a potential or local offer of opportunities that enable interested, skilled, and motivated people to achieve certain results. Not all individuals will perceive the opportunities or benefit from them. The relation between a knowledge milieu and the actions of individuals is full of serendipities. The discourses and social interactions in a certain location and the effects of a knowledge environment cannot be forecast, but only analyzed after interactions and problem solving have taken place or after certain stages of a research process or a career have ended.

Spatial Differences of Knowledge

New knowledge always starts as local knowledge. It is created in particular places and contexts. Local knowledge becomes regional or global knowledge only if it is understood and accepted elsewhere. The speed at which new knowledge diffuses over space depends on the category of knowledge, the interest that the producer (inventor) has in sharing his or her knowledge, the reputation of the institution within which the new knowledge is produced, the platforms on which the new knowledge is introduced, the codes (e.g., languages and mathematical formulas) and channels by which the information is presented, the prior knowledge that the receivers of the new knowledge need in order to understand the message, the availability of the technology necessary for applying or reproducing certain types of knowledge, and the varying inclination of people to accept a specific kind of knowledge (for details see Meusburger, 2009). Prior knowledge is not something people possess. It is constantly developed in a way similar to the knowledge spiral described by Nonaka and Takeuchi (1995: p. 71). Many spatial

disparities of knowledge evolved from keeping knowledge secret as long as possible. Keeping knowledge secret and exploiting information gaps are well-established ways to be more successful than competitors or gain large profits.

Spatial disparities in knowledge, competence, professional skills, and technological standards have existed since early human history. Key factors in the competitiveness and survival of social systems include skilled, experienced, highly educated, and well-informed elites; informational advantage of merchants and political institutions; inventiveness and creativity; superior technologies giving military supremacy to a territory or state and increasing the efficiency, productivity, and transport capacity of industries; seminal scientific achievements; and a highly skilled workforce. Superior knowledge makes it possible to evaluate situations more realistically than less-informed competitors are able to do, to foresee upcoming problems and unintended consequences of actions earlier than others, to increase productivity, and to replace existing technologies with newer, better performing ones. However, power and knowledge are employed and exercised mainly within organizations and institutions 'through a netlike organization' (Foucault, 1980: p. 98; see also Blackler, 1995; Glückler, 2013); without the help of institutions, organizations, and networks an individual agent is rarely able to transform knowledge into power.

Geographers argue that many spatial disparities of knowledge are not ephemeral, transitional phenomena but remarkably persistent over time. Centers of knowledge (and power) have shifted over the centuries, but spatial differences of knowledge have never disappeared and are a fundamental structural attribute of any society with an elaborate division of labor. Time lags in the circulation and adoption of new knowledge and spatial mobility of highly and lowly educated people have repeatedly created new spatial disparities of knowledge. Traditional neoclassical economists used to assert that codified knowledge is a public and tradable commodity and that new communication devices and transport technologies would eliminate or diminish spatial disparities of knowledge. These misjudgments have resulted from an inadequate concept and definition of knowledge, a neglect of the role of the spatial context, an excessively naive model of communication, and failure to recognize the importance of the time dimension. In many competitive situations, it is not knowledge per se that counts but rather the point in time when new information is acquired or when new knowledge and skills are generated or utilized. The economic value of knowledge and information varies with time. On the stock market, receiving information just minutes or even seconds in advance is enough to net huge profits. In academia, days or weeks can decide which author goes down in history as the one credited with a given scientific discovery.

Methodological Problems of Localizing Knowledge

The first crucial question for empirical work on the geography of knowledge is how intangibles such as knowledge can be localized. The answer depends on the research question, the scale of inquiry, and the category of knowledge investigated. Knowledge is not floating in the air; it is bound to agents or bearers. With human bearers of knowledge, the places of birth, study, work, and residence, as well as the spaces of interaction are usually documented in biographies. This background reveals the environments in which a person was socialized and trained and the places where she or he pursued creative ideas or had professional breakthroughs. It gives insight into a person's networks, career mobility, and other place-specific information. Material bearers of knowledge (e.g., intelligent robots) and immaterial ones (e.g., theoretical concepts, scientific methods, patents, ideologies) can be related to the places where they were invented and later diffused. It is possible to localize the places where exceptional research results have been achieved, new philosophical schools founded, new scientific questions asked, new scientific instruments used for the first time, or seminal scientific discussions conducted (Meusburger and Schuch, 2012).

The second question is: which categories of knowledge are or are not suitable for localization in space and on various scales of investigation. Unlike the meaning of the terms *educational attainment* and *educational achievement*, whose spatial variations can be studied with relatively well-defined indicators for small spatial entities, the meaning of the word *knowledge* is broad and elusive. It is quite clear that not all categories of knowledge can be localized. Scholars of social sciences and humanities focusing on the actions (behavior) of individual human beings regard knowledge primarily as capability or capacity for social action (Stehr, 2001). From that point of view, knowledge is rooted in individual persons and becomes manifest in their cognitive and intellectual capacities, professional competence and achievements, and performance in problem solving and decision making. At this micro level of analysis, it is possible to study the spatial dimension of many categories of knowledge. But at higher levels of spatial aggregation, knowledge can be grasped only with the help of indicators representing *input* in knowledge generation (e.g., research resources) and *outcomes* of learning, research (e.g., scientific publications, patents, high-tech products), problem solving and experience. The challenge is to find indicators representing such outcomes of learning and achievements. Such indicators may include professional achievements and skills, scientific awards, research results, inventions, patents, high-tech products, scientific reputation of a university or research institute, new organizational structures, specific institutional rules, cultural value systems, and other outcomes of learning and not learning.

Categorizations and Definitions of Knowledge

Knowledge can be theorized, categorized, defined, and operationalized in many different ways, depending on the discipline, research questions, theoretical approach, and scale of inquiry. Philosophical questions such as 'what is (objective) knowledge,' 'what is truth,' 'what is reality,' and 'what are the differences between opinion, belief, and knowledge' have been discussed in thousands of publications (for details see Abel, 2008). The discussion here is confined to some of those categories and definitions that are important for the explanation of spatial variations of knowledge.

Knowledge Is Not Equivalent to Information

As a large part of knowledge can be codified and because codified knowledge can be transformed into information, some authors, especially mainstream neoclassical economists, have argued for decades that knowledge and information are more or less the same (for an overview and critique of this approach see Ancori et al., 2000: p. 256; Cowan et al., 2000: p. 221; Meusburger, 2009, 2013: pp. 16–17). Granted from the viewpoint of the person who generates new knowledge or tries to communicate his or her knowledge to other people the distinction between information and knowledge becomes blurred. From the standpoint of a message's recipient, however, the difference between knowledge and information is rather distinct.

The fact that codified knowledge is made public, shared with others, and made available for free does not mean that it is understood, accepted, or used by all who have access to it. Ready access to information is only one side of the coin. The other side is about the cognitive abilities, interests, training, educational achievement, and prejudice of recipients and the milieu they are embedded in.

As soon as the communication process between a generator and receiver of new knowledge, the spatial dissemination of information, and spatial disparities of knowledge become topics of research, a distinction between knowledge and information becomes indispensable. The discrepancy between knowledge and information is also manifest in the contemporary simultaneity of the superabundance of information and scarcity of knowledge.

Categorizations of Knowledge

According to Abel (2008), it is important to distinguish first between a narrow and a broad notion of knowledge. The narrow concept of knowledge "refers to knowledge obtained by a methodically well-regulated procedure bound to justification, truth, and verification. It is essential with such knowledge that one be able to talk about it and that it be communicable, transferable, intersubjectively verifiable, and interchangeable" (p. 12). Scientific knowledge falls into this category. "The broad notion of knowing and knowledge refers to the ability to adequately grasp what something is about (e.g., what a sentence or a picture is about) on the one hand and the domain of human capacities, competencies, skills, practices, and proficiencies on the other" (p. 12).

A second categorization (Abel, 2008: p. 13) distinguishes among the following four types:

1. *Everyday knowledge* (e.g., knowing where the bus station is, knowing the price of a good, knowing the results of yesterday's soccer matches).
2. *Theoretical knowledge* (e.g., knowing that the sum of the angles in a triangle equals 180°).
3. *Action knowledge* (e.g., knowing how to drive a car, play violin, or perform a heart surgery).
4. *Moral or orientational knowledge* (e.g., knowing what is right and wrong). This kind of knowledge is generated and cultivated by religions, ideologies, and collective memories. Its truth claims are not open to scientific reasoning (for details see Abel, 2008: p. 12). For pragmatic reasons, categories 1, 2, and 3 are sometimes subsumed in the category called 'factual knowledge.' The categories factual knowledge and orientational knowledge are frequently used when the mutual relations between power and knowledge are an issue.

A very popular distinction is between explicit (codified) and implicit (tacit) knowledge. Tacit knowledge means those aspects of knowing that are implicit in situations of perceiving, speaking, thinking, and acting but not made explicit, i.e., not disclosed on the surface (for details see Collins, 2001). Some authors use the concept of tacit knowledge as a kind of umbrella term for nonverbal and nonpropositional knowledge. Unfortunately, "the terminology and meaning of 'tacitness' in the economics literature [have] drifted far from its original epistemological and psychological moorings [and have] become unproductively amorphous" (Cowan et al., 2000: p. 213).

Verbal knowledge (knowledge that can be articulated by using linguistic expressions) can be distinguished from nonverbal knowledge (e.g., visual, pictorial, or musical knowledge). One can also make a distinction between propositional knowledge (knowledge that can be articulated in a linguistic proposition such as 'Picasso was a painter' or 'Berlin is the capital of Germany') and nonpropositional knowledge that cannot really be grasped by words (such as knowing how to understand a bodily movement but not being able to put it into words). "Forms of nonpropositional knowledge also become manifest in a person's practical skills, pictures, shapes, sounds, gestures, or mental images" (Abel, 2008: p. 25). Very important is the differentiation between knowledge relating to matters of fact and knowledge based on skills and abilities.

When spatial dissemination of knowledge becomes an issue, researchers also need a vertical differentiation of codified knowledge (Meusburger, 2013). After first considering the time and costs of acquiring the prior knowledge necessary to understand particular information, one should distinguish between lower and higher levels of codified knowledge. The gap between knowledge and information grows with each level. The lowest category, everyday knowledge, is easily understood by almost everyone. Whoever has access to this kind of knowledge is able to use it, provided he or she understands the language. This type of knowledge corresponds more or less to the traditional neoclassical economist's standard view that codified knowledge is equivalent to information, that codified knowledge is a public, tradable, and spatially mobile commodity, and that spatial disparities of knowledge are only short lived.

All other, higher levels of codified knowledge require the information recipient to possess a certain body of prior knowledge (sometimes years of study, professional experience, and research) that will enable this person to understand the available information, evaluate its relevance and usefulness for achieving goals, and integrate it into his or her own knowledge base. Having access to higher levels of codified knowledge is not equivalent to gaining knowledge.

Only everyday knowledge, which is the least important type for economic competitiveness and innovation, is ubiquitously available (at least theoretically) if it is assumed that all places have the necessary technical equipment and that all people

have an equivalent inclination to receive the message. Workplaces of actors commanding levels of codified knowledge higher than everyday knowledge tend to be spatially concentrated. It goes without saying that other categories of knowledge not discussed in this article are also frequently used in geography of knowledge.

The Process of Communicating Different Categories of Knowledge from A to B

The spatial diffusion of new knowledge and the migration of scholars and highly skilled professionals are key issues in geography of knowledge. However, the spatial dissemination of knowledge is much more complex and more place-dependent than the simple sender–receiver model of information theory suggests.

The most efficient or reliable way to transfer specialized high-level knowledge or competencies from place A to place B is through migration of those people who generated or currently command that knowledge. No other attempts at transferring high-level knowledge (in the form of texts, figures, or instruments) guarantee that the knowledge will be fully understood, accepted, or applied by the receivers as the sender intended. When studying the spatial circulation of different categories of knowledge, one has to take into account the cognitive processes of sender and receiver and the intervening variables and learning loops within the communication process. Many authors overemphasize the knowledge producer's ability to codify knowledge into information. They also underestimate or neglect the cognitive processes of the receiver and overlook the role of prior knowledge, a receiver's ability to read, understand, and accept certain kinds of information and to integrate it into his or her knowledge base. The producers and transmitters of knowledge have limited influence on the extent to which their message is understood, accepted, and processed or the way it is translated and interpreted elsewhere (Meusburger, 2009, 2013).

Higher levels of knowledge can be transferred from one person to another only if the receiver's prior knowledge, training, skills, experience, or capabilities are broadly equivalent to those of the sender. A certain type of knowledge may be perfectly codified in text and equations, published in international journals, and offered for free on the Internet, but it may be understood by only 100–200 theoretical physicists worldwide. The rest of the world's population may not have acquired the prior knowledge and experience necessary to read and comprehend the text, formulas, and equations and to integrate this new information into their own knowledge base.

Persons who have not completed years of study and research in molecular biology or theoretical physics have little or no use for the available scientific publications in these fields. Some types of scientific knowledge cannot be simply transferred from A to B. To be assimilated, they must be replicated in B with expensive experiments in sophisticated laboratories. Owing to these preconditions, higher levels of knowledge often circulate only among the upper echelons of the urban hierarchy, among university towns, or among centers of an economic domain, and they leapfrog large areas. The generation of new high-level knowledge generally precipitates new knowledge divides (e.g., digital divide).

Each step of the communication process illustrated in Meusburger (2009: p. 35) has a high degree of actor-, community-, and place-dependent contingency letting some information pass in its original meaning but withholding, transforming, or distorting other information. In this context, the term *filter* is used as a metaphor for various cognitive processes, mind-sets, and power relations that influence the selectivity of perception; the processing, evaluation, and interpretation of incoming information; and the enactment of knowledge as practice.

Relations between Knowledge and Power

In the study of the persistence and continuous reproduction of knowledge disparities between centers and peripheries, two issues have become crucial: coalitions between knowledge and power, and the attractiveness of power centers for highly skilled professionals. Why do agents representing the highest echelons of power and knowledge so frequently build coalitions? And why do they seek (relational) proximity to each other? On the one hand, it is in the interest of power to bind knowledge into networks of assent. Both instrumental power (i.e., the capacity to make others do one's will and the ability to control, regulate, and dominate) and associational power (i.e., the power to do things by acting in concert or by using institutional mediation) depend on experts, scientists, research institutions, intelligence services, and think tanks to achieve and maintain influential status for themselves. Their knowledge, expertise, and competence are needed in order to examine a situation as precisely as possible, to perceive upcoming problems earlier than others, to offer solutions to problems that have to be solved and to retain political, economic, military, or cultural supremacy.

Upper echelons of political power also need the support of the representatives of orientational knowledge (priests, intellectuals, artists, propagandists, and ideologues) who share their norms, values, and collective memories; vindicate their actions; and legitimate their power. Experts of orientational knowledge are trained and experienced in the art of influencing, convincing, and manipulating people. Their task is not to analyze a 'real situation' or to seek 'objective facts' but rather to make moral judgments; interpret events; create beliefs, mind-sets, and collective memories; sustain the internal cohesion and motivation of their social system; mobilize loyalty; and excuse actions criticized by opponents.

Advisers, counselors, scientists, experts, priests, and intellectuals derive part of their power from their claim to know better than the majority of people (Stehr, 1992), to foresee the consequences of an intended action, and to be able to forecast future events and developments. When having to make important decisions, those in power in earlier centuries engaged dream interpreters, oracles, and priests, all of whom claimed they could communicate with the gods (or ancestors) or represent God's will on Earth. Today, power brokers and decision makers rely on think tanks, scientists, and other experts.

Just as power depends on knowledge, many bearers of factual knowledge and orientational knowledge need the

support of power and seek relational proximity to power. Scientists and experts in various domains often have to prove their usefulness to power in order to secure the privileges and resources they need for their work. Often the state, a political party, center of economic power, or prestigious journal lends authority to experts. Power often ignores those experts who do not serve its interests. Therefore, experts authorized by state agencies may be opposed by experts supporting the interests of local people. Most experts and intellectuals want to be concerned with the essential in existence; they strive for influence, recognition, and reputation. Network centrality, or relational proximity to power, demonstrates authority, importance, and prestige. It determines access to valued resources and information unavailable to people at the margin. Proximity to and trustful relations with those in power increase the opportunities of experts and scholars to influence important political decisions. Even dissidents and other intellectuals opposing those in power have to operate in centers of power in order to elicit response in the media and create a viable alternative.

Those in power have always attempted to exercise control over institutions of knowledge generation and information distribution, fortunately with limited success. Over the centuries, knowledge was frequently used as a means to discipline, dominate, exclude, and manipulate people (Foucault, 1969). Production and distribution of knowledge and information are often associated with censorship, forgery, secrecy, and propaganda. Many national memories and histories are socially constructed according to the interests of dominant groups and contested by other groups. The representations of the culture, history, and geography of colonies by imperial powers (Said, 1978; Gregory, 1998) are perfect examples of how culture (knowledge) underwrites power and how power elaborates culture (knowledge).

Distribution of Knowledge-Intensive Jobs in the Hierarchy of the Urban System

The vertical division of labor (bifurcation of skills), the differentiation of complex large systems, the professionalization and bureaucratization of labor relations, and various other trends induced a spatial concentration of power and knowledge in upper levels of the urban hierarchy. This uneven distribution of jobs by skill level also influences the selective migration of employees with higher or lower levels of educational achievement, as well as the uneven distribution of creative milieus. Important decision makers, scientists, experts, artists, and intellectuals striving for prestige, influence, and success sooner or later find their place of work in one of the centers of their domain or will create a new center in their chosen field. Knowledge centers attract a large share of their highly educated workforce from other regions, and rural or peripheral areas lose most of their talented youths to the centers. Both processes significantly transform the places concerned and contribute to the long persistence of center-periphery disparities.

Why do workplaces of highly educated employees in various economic sectors tend toward such high spatial concentration in a few centers, whereas low-skilled routine activities in production and administration tend toward decentralization as shown in Tables 1 and 2?

Table 1 Spatial concentrations of jobs for Hungarian university graduates in Budapest and the capitals of the 19 Hungarian counties (1980)

Economic sectors or professions offering jobs for university graduates	*Percentage of jobs located in Budapest and the capitals of the 19 Hungarian counties*[a]
Foreign trade	98.7
Personal and business services	96.1
Organization and development of housing	96.0
Science and research	88.7
Cultural services	88.6
Banking and finance	87.8
Transport and traffic	86.6
Telecommunications	86.5
Public administration	80.3
Machinery	79.9
Light industry	74.9

Note: Special analysis of the 1980 Hungarian census.
[a]Budapest and the capitals of the 19 counties accounted for 35.4% of the national population in 1980.

Table 2 The concentration of high- and low-qualified jobs in Hungarian towns and villages up to 5000 inhabitants (1980)

Professions and occupations of persons with a university degree	*Percentage of all Hungarian jobs located in cities and villages smaller than 5000 inhabitants*[a]
Journalists	0.3
Leading organs of state power and central administration	0.4
Foreign trade	0.4
Community services	0.6
Banking and finance	0.7
Telecommunications	0.8
Leaders of party and mass organizations	1.0
Law and public order	1.4
Jobs for university graduates in total	7.4

Note: Special analysis of the 1980 Hungarian census.
[a]Villages up to 5000 inhabitants accounted for 32% of the national population in 1980.
Source: Meusburger, P., 1997. Spatial and social inequality in communist countries and in the first period of the transformation process to a market economy: the example of Hungary. Geographical Review of Japan 70 (Ser. B), 133. Reprint with permission.

The first explanation draws on organization theory and the meritocratic principle. No social system can completely avoid faulty analyses, misjudgments, or wrong decisions. But the fewer mistakes it makes in important situations of problem solving and the more adaptive it is, the more likely its long-term competitive survivability will be. In social systems, knowledge, skills, and experience have a function similar to that of redundancy in technical systems. They reduce uncertainty and enhance the chances of survival. A social

system, institution, or state acts in its own interest when it fills its vital positions of information processing, decision making, planning, coordination, and control with well-educated, experienced persons. In particular, people and subsystems whose positions are fraught with uncertainty and whose decisions have abiding consequences for the entire system require advanced skills, superior knowledge, and vast experience.

In a dynamic and competitive society, the skills and knowledge needed for the chief functions of a social system striving for success will always be scarce. Therefore, the first crucial question is where to locate scarce knowledge and skills within a social system's structure of decision making. In bureaucratic systems and in systems confronted with low degrees of uncertainty, decision making, problem solving, research, and planning shift to the upper levels of the system's hierarchy, so the lower levels are characterized by routine activities and workplaces for people with lower skills. In systems dealing with a dynamic, complex environment and dealing with constantly changing, unpredictable, one-time transactions, lower ranking and decentralized positions, too, need people having a high level of competence and skills (for details see Mintzberg, 1979).

The second question is where to locate valuable and scarce knowledge and skills spatially. Routine activities for which there are plans, rules, and common procedures call for fewer learning processes, lower skills, and less face-to-face contacts with other organizations than nonroutine activities do. Routine activities are coordinated predominantly by indirect contacts (phone, emails, and letters). Therefore, they can be situated in a great number of relatively smaller cities, even rural areas, as long as the traditional location factors such as transportation and wage costs make it feasible. The harder it is for decisions to be governed by guidelines, plans, regulations, or so-called hard information, the more dynamic and competitive the social environment, and the greater the uncertainty about the future, the more necessary it is to have frequent and spontaneous face-to-face contacts with knowledgeable and well-informed decision makers and highly skilled specialists of other organizations and domains. At the highest levels of management the need for spontaneous face-to-face contacts and valuable networks can be met only in a few large centers offering a large diversity and density of knowledgeable specialists and prominent decision makers of various domains. Trustful relations and frequent face-to-face contacts with leading decision makers in government, research, finance, consulting, media, and big business offer access to early knowledge about important tendencies and innovations and provides crucial information to an organization's ranking members facilitating their quick response and adaptation to new situations and developments.

The second explanation for the spatial concentration of jobs for important decision makers and highly specialized professionals is that places and milieus, especially centers and peripheries, have symbolic meanings. The center of a social system or of a domain is defined as the place where its highest authority is located. By definition, the place of maximum access to the system as a whole, a center is associated with power, authority, dominance, prestige, control, and influence. It claims preeminence with regard to expertise and competence. The term periphery symbolizes dependency, marginality, backwardness, and lower prestige.

Further Perspectives

As knowledge concerns a broad range of activities, a large number of emerging fields and further perspectives could be mentioned. From a geographer's point of view, at least three issues should receive more attention. The first comprises the questions: What is the essence of knowledge milieus and creative environments? How can the impact of environments on knowledge generation be theoretically conceptualized and empirically scrutinized? What kinds of processes and policies help to create knowledge-based regional advantages? Are creative milieus bound to certain types of cities? If they emerge in rural peripheries, too, then under which external conditions and in which domains will they form?

Most of the research in the geography of knowledge has dealt with positively valued aspects of knowledge generation, such as research, innovations, or cultural and intellectual exchange. But social relations are not based only on selfless knowledge sharing, transparency, and open innovation. A second group of new perspectives could highlight the darker sides of knowledge generation, e.g., manipulation and censorship of information, cultural imperialism, spying, using asymmetries of knowledge for fraud, and so on. Many hegemonic practices are based on asymmetries of knowledge and the exploitation of knowledge gaps.

A third group of future perspectives can be seen in the field of spatial disparities of orientational knowledge, e.g., in spatial disparities of the predominance of ideologies, mentalities, collective memories, and prejudice, and in clashes of different bodies of orientational knowledge in ethnically diverse areas.

Knowledge Representation

Ernest Davis, New York University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In artificial intelligence, knowledge representation is the study of how the beliefs, intentions, and value judgments of an intelligent agent can be expressed in a transparent, symbolic notation suitable for automated reasoning. From a purely computational point of view, the major objectives to be achieved are breadth of scope, expressivity, precision, support of efficient inference, learnability, robustness, and ease of construction. Knowledge-based techniques have been applied successfully for many computational tasks including text interpretation and cognitive robotics. Many different general architectures have been used for knowledge representation, including first-order logic, other formal logics, semantic networks, and frame-based systems. The representation of temporal knowledge is both a problem of central importance in knowledge representation and an archetype of the kinds of issues that arise in developing representations for various domains. The use of machine learning techniques for the automatic construction of knowledge bases and knowledge representations is difficult, but has achieved some degree of success.

Knowledge Representation: Ideal and Reality

The knowledge-based approach to artificial intelligence (AI) conjectures that a large component of any AI system with broad intelligence will be a knowledge base: a transparent, symbolic representation of the agent's beliefs, intentions, and value judgments, together with reasoning processes that modify the knowledge base in rational ways. Perceptual and motor processes connect the knowledge base to the outside world. The field of knowledge representation (KR) is the study of how such a knowledge base can be constructed (van Harmelen et al., 2008).

The representation of knowledge in a knowledge base should be symbolic, transparent, and modular. That is, the atomic elements of a knowledge base are symbols, each of which has an associated meaning. It is possible to identify small substructures of the knowledge base that correspond to specific beliefs, judgments, and intentions. For example, the belief that Holbein painted a portrait of Thomas More in oil might be represented in a predicate calculus formula like

$$\exists_x \text{ Oilpainting}(x) \ \wedge \ \text{Painter}(\text{Holbein}, x) \wedge \text{Depicts}(x, \text{ ThomasMore})$$

or in a fragment of a semantic net (Figure 1).

Here the symbols are '∃' (meaning 'there exists'), 'x' (a variable), '∧' (meaning 'and'), 'OilPainting', 'Painter', 'Depicts', 'Holbein', and 'ThomasMore'. The parentheses and the comma indicate the syntactic structure.

Not every belief of the agent can be explicitly expressed in the knowledge base. For example, someone who knows that Holbein painted a portrait of Thomas More will also know that Holbein knew how to paint, that Thomas More was painted, that Thomas More was born before Holbein's death, and so on. These ancillary beliefs are not each separately represented in the knowledge base. Rather, they are derived as needed by combining the particular fact with general knowledge about painting.

The construction of a broadly intelligent artificial agent is the ultimate objective for AI, but realistic short-term projects focus on specific, narrowly defined tasks. For such a limited project, the problem of KR is one of finding data structures that express the knowledge needed for the particular application.

Thus broadly construed, the problem of KR would appear to be equivalent to computer programming generally. Any program, after all, uses some data structures and incorporates some kind of knowledge. The field of KR is distinguished in its focus on a broad range of fundamental knowledge, particularly commonsensical world knowledge; on representations that are highly expressive, particularly of various natural forms of partial knowledge; and on forms of reasoning that arise in intelligent tasks. As AI is the study of tasks that are easy for people to carry out but difficult to automate, so is KR the design of data structures that express knowledge that people deal with easily, but are hard to encode in a data structure. The design of a KR can be very roughly divided into five parts.

1. Architecture: The design of general-purpose schemas for KR and procedures for reasoning with these schemas.
2. Content: The characterization of the knowledge that is to be represented, particularly for fundamental categories such as time, space, and communication.

Figure 1 Fragment of a semantic net.

3. Implementation: The specifics of instantiating the representation as a data structure and the reasoning process as a procedure.
4. Interface: The connection of the knowledge base to an external application.
5. Learning: Constructing the knowledge base, or parts of it, automatically by the analysis of a data corpus.

Desiderata

The design of a KR will generally aim toward the following objectives:

Scope: A KR for a limited application should cover all relevant aspects of the relevant domains. For a broadly intelligent aspect, an adequate KR theory must, first, describe the specifics of the representation of fundamental and universal human thought, such as time, space, simple physical categories, the human mind, and human relations (Davis, 1990; McCarthy, 1968), and, second, describe a general representational architecture that is applicable to any comprehensible object of thought.

Expressivity: The KR should be able to express the forms of partial and incomplete knowledge that naturally arise for the desired application.

For example, a standard form of representation is a collection of tables of values, known in computer science as a 'relational database'. Table 1 displays a table of paintings and a table of artists.

However, even within its narrow topical scope, such a representation may not achieve reasonable expressivity, because there is no way to express plausible partial states of knowledge such as

Delacroix was a generation older than Monet.
Rembrandt painted many oil paintings.
The Sistine Chapel and the sculpture of David were created by the same artist.

If such partial states of knowledge are important in the application, then a more expressive language must be found.

Here is another example: it is tempting to represent spatial information using a representation that corresponds to a single picture of the scene, sometimes called a diagrammatic representation (Glasgow et al., 1995). Such representations are easily understood and support efficient inference. However, they cannot be used to represent partial information. For instance, an agent might know that A is a mile from B and that A is a mile from C without knowing the distance from A to C. However, it is not possible for a single picture to display the distances from A to B and from A to C without committing itself to some particular distance between B and C. Therefore, this and other similar states of knowledge cannot be represented in a diagrammatic representation.

Table 1 Relational database of paintings and artists

Work	*Medium*	*Genre*	*Artist*
Last Supper	Fresco	Religious	da Vinci
Melancholia	Drawing	Allegory	Durer
Thomas More	Oil	Portrait	Holbein
Mona Lisa	Oil	Portrait	da Vinci

Artist	*Country*	*Birth*	*Death*
Durer	Germany	1471	1528
Holbein	Germany	1497	1543
da Vinci	Italy	1452	1519
O'Keefe	USA	1887	1986

Precision: The meaning of a KR should be unambiguous, and, as far as the subject matter allows, well defined.

Support for reasoning: It must be possible to model the processes of reasoning involved in cognition in terms of well-defined operations over the KR. For example, as mentioned above, an agent who knows that Holbein painted a portrait of More should be able to conclude that Holbein knew how to paint, that More was born before Holbein died, and so on.

Efficiency of reasoning: The implementation of reasoning operations over the KR must also be efficient. Depending on the application, it may be necessary to draw conclusions from a large knowledge base in a fraction of a second.

Learnability: The KR should support modules that can learn from experience and can generalize individual cases to general rules.

Support for uncertainty: To be useful, a knowledge base cannot be limited to information known with certainty. Rather, the KR must be able to express relative degrees of certainty, and reasoning modules must use these (Pearl, 1988; Halpern, 2003).

Robustness: The information in a knowledge base will sometimes be wrong or corrupted. The effects of an error in the knowledge base should be limited in scope.

Ease of construction: Ideally, the information in a large knowledge base can be collected automatically or semi-automatically from existing data sets. If the knowledge base must be constructed manually, then a notation that can be used by users with little technical expertize is obviously preferable to one that requires a KR expert. The less the human labor, especially expert labor, required to build a knowledge base, the better.

Interface: A KR should support a suitable interface to the user or the application.

Expressivity and precision are features both of the architecture and of the content of a knowledge base. Scope is chiefly a feature of content, although expressivity and therefore architecture do bear on scope; some domains inherently require a very expressive language. Robustness, ease of construction, and support for reasoning, learning, and uncertainty are primarily features of the architecture. Efficiency of reasoning depends on the architecture, procedures, and class of problems being solved.

Applications

KR and automated reasoning have been applied, with greater and lesser degrees of success, to a very wide range of intelligent tasks. Here we will discuss briefly the representational issues involved in two particular important categories of applications: the interpretation of natural language text and action planning for robotic systems.

Text Interpretation and Information Retrieval

Many useful computational tasks involving text, such as document retrieval, can be effectively carried out based purely on superficial features of the text, such as word counts, with no representation of the meaning of the text or knowledge of the domain it refers to. However, tasks such as answering questions necessarily engage with the meaning of the text; therefore, performing these well requires a representation of the text and of the underlying domain. Other tasks such as machine translation, summarization, and information extraction can be carried out without using KR to an accuracy that may be useful but cannot be carried out with very high quality. Basic components of text interpretation, especially disambiguation, often require the application of world knowledge. For example, in interpreting the sentence "Jane knocked on Susan's door, but she did not answer", disambiguating 'she' to mean 'Susan' requires understanding the conventions of answering knocks. (By contrast, if the sentence ended, 'but she did not get an answer', then 'she' would refer to Jane.)

Attempts to use knowledge-based techniques in text understanding vary widely in terms of the depth of the knowledge represented, the breadth of the subject matter, and the degree to which the knowledge base is created manually as opposed to assembled automatically. At one end of the spectrum are systems that form a complete logical representation of the explicit and implicit content of the text, and that draw on a detailed knowledge base in carrying out inferences from the text (Balduccini et al., 2008); these necessarily are highly limited in scope, and require massive human labor. At the other end are systems whose knowledge base is derived purely from statistical analysis of a corpus of texts; the knowledge base is essentially a table of correlations between words (Dumais, 2005).

As of the time of writing, perhaps the greatest successes have been achieved by information extraction systems that lie somewhere between these two extremes. Information extraction systems are designed to extract from text information of a restricted, often predetermined form, such as the employee, company, and position in a business page story about hiring a new executive. The systems use a combination of general linguistic analysis, specific linguistic patterns, pre-existing online language tools such as WordNet, and basic background knowledge of the domain such as a hierarchy of semantic categories and semantic constraints (e.g., an employee must be a person). Some parts of these are constructed manually for the particular task; some are drawn from existing manually created tools; some are developed automatically, using machine learning techniques, both supervised and unsupervised.

Robotics and Planning

The application of knowledge-based techniques to robot control, sometimes called 'cognitive robotics,' has focused primarily on high-level planning, although researchers have also looked at integrating automated reasoning with lower level manipulation (Reiter, 2001; Ghallab et al., 2004; LaValle, 2006). Central issues in cognitive robotics include the following:

- *Causal modeling*: Developing a theory that characterizes how the world changes, both in response to the robot's actions, and as a result of processes independent of the robot.
- *Modeling perception*: A high-level model of what the robot can expect to perceive while executing a plan, and how it can use the perceptions to guide its actions.
- *Developing a high-level language of plans*: In the simplest case, extensively studied, a plan is simply a sequence of actions to be executed, but in richer domains, a plan may involve conditionals, loops, interruptions, concurrency, and so on.
- *Projection*: Predicting what will happen if the robot attempts to execute a specified plan.
- *Planning*: Constructing a plan that achieves a specified goal.
- *Multiagent planning*: Constructing a plan for an environment with multiple agents. Agents may be cooperative, independent, or antagonistic; if cooperative, there may or may not exist a centralized control (the boss).

A number of autonomous robotic systems, including the Mars rover, have made some use of knowledge-based reasoning.

Architectures

A number of KR architectures are briefly surveyed below. The particular architectures included here have been included, in part because of their importance in KR research and applications, and in part to illustrate the range of possible approaches to KR.

Logic-Based Systems

A logic-based system represents knowledge as a set of sentences in a logical language. Reasoning is implemented as inference procedures that carry out deductive proofs authorized within the logical theory (Geneserth and Nilsson, 1987).

A logical theory characteristically consists of three parts:

- A syntax, which specifies what kinds of symbols are used, and how they are combined to form sentences.
- A semantics, which specifies how the meaning of a sentence relates to the meanings of the symbols it contains.
- A proof theory, which specifies what combinations of sentences constitute deductive proofs.

For example, first-order logic (also known as the predicate calculus) is the most widely used logic in KR. In first-order logic, there are seven kinds of symbols:

- Constant symbols represent individual entities. For example, the symbol Ad1517 may represent the year 1517.
- Predicate symbols represent properties or relations. For example, Painter may represent the two-place relation of a person painting a painting. Precedes may represent the relation of one event preceding another.
- Function symbols represent mappings. For example, BirthOf may represent the one-place mapping of a person to the event of his/her birth. CreationOf may represent the mapping of an artifact to the event of its creation.
- The Boolean operators are '$\wedge$' meaning 'and'; '$\vee$' meaning 'or'; '$\sim$' meaning 'not'; and '$\Rightarrow$' meaning 'implies'.
- Variables such as x, y, z represent indeterminate entities.
- The quantifiers are '$\forall$' meaning 'for all' and '$\exists$' meaning 'there exists'.

- Finally, the comma and the open and close parentheses indicate the structure of the sentence.

Constant, predicate, and function symbols are known as nonlogical symbols; they may be chosen, and their meanings assigned, by the designer of the knowledge base. Boolean operators, quantifiers, variables, and grouping symbols are known as logical symbols; their meanings are fixed by the logic. The distinction is roughly analogous to the distinction between open and closed categories in linguistics, or to the distinction between identifiers and reserved words in programming languages.

The syntactic rules for first-order logic establish that these symbols can be put together to form sentences such as the following:

$$\forall x,y\ \text{Painter}(x,y) \Rightarrow \text{Precedes}(\text{BirthOf}(x),\text{CreationOf}(y)) \quad (1)$$

The semantic rules establish that, given the above assignments of meanings to the symbols Painter, Precedes, BirthOf, and CreationOf, the sentence is true just if the birth of every painter precedes the creation of all his/her works. The proof theory establishes that, given sentence (1) above and the sentence Painter(Holbein,MorePortrait), it is possible to infer the following sentence:

Precedes(BirthOf(Holbein),CreationOf(MorePortrait))

This inference is valid regardless of the meaning of the nonlogical symbols (Mates, 1972).

Many other logics have also been used for KR. Some of these extend first-order logic to achieve greater expressivity. Modal logics define a variety of operators on sentences. For instance, given a base sentence, such as 'Bill Clinton is President,' sentences such as 'Bill Clinton was President,' 'Al Gore knows that Bill Clinton is President,' or 'Bill Clinton ought to be President' can be generated by applying temporal, epistemic, or deontic operators (Turner, 1984). Fuzzy logic allows the use of vague terms that hold to greater and lesser degrees; for example, 'George Washington was tall' is reasonably true, while 'Wilt Chamberlain was a tall person' is absolutely true (Zadeh, 1987). Probabilistic logics allow sentences to be tagged with a measure of certainty (Halpern, 2003).

Other KRs use logics less expressive than the predicate calculus in order to carry out inference more efficiently. For example, in the propositional calculus, the only logical symbols are Boolean operators, and a separate symbol must be used for each atomic proposition. Thus there is one symbol for the proposition, 'Leonardo painted the Last Supper,' another for the (false) proposition, 'Rodin painted the Last Supper,' and so on. General rules like formula (1) above can then only be stated by stating every instance for every pair of a painter and a painting. Despite this proliferation of symbols and formulas, however, as long as the underlying domain is not too large, it is often more effective to use the propositional calculus than the predicate calculus, because the best methods of inference known are much faster for the propositional calculus than the predicate calculus (Gomes et al., 2008).

The chief virtues of logic-based representation are precision and modularity. The meaning of a formula in a logic-based representation is completely and exactly fixed by the logic and the meaning of the symbols included. It is independent of any other formula in the knowledge base, and any other aspect of the knowledge base. Moreover, in a monotonic logic, the validity of any proof depends only on the formulas used in the proof and not on any other aspect of the knowledge base. Another important virtue is that procedures for deductive inference over logic-based knowledge bases are known. These procedures characteristically generate only valid inferences and all valid inferences (in the technical jargon, they are sound and complete), and, are in practice, they can often be implemented so as to find useful answers quickly.

Their chief drawback is difficulty of use. Building a knowledge base in a logic-based representation inevitably requires a large investment of expert labor. Moreover, even experts in KR find the encoding of complex domains in logical languages surprisingly difficult and error-prone. Logic-based languages also tend to be fragile. In principle, any inconsistency in any part of a logical theory invalidates the entire theory, and in practice small and subtle inconsistencies in foundational parts of a logic-based knowledge base can lead to bizarre and unpredictable results.

Semantic Networks

A semantic network consists of labeled nodes connected by labeled arcs (Figure 2). A node may represent an individual

Figure 2 Semantic network consisting of labeled nodes connected by labeled arcs.

such as Holbein or a category such as oil paintings. An arc represents a two-place relation between nodes, such as the relation 'painter' between a work of art and a person.

The most important arcs in any semantic network are those labeled 'INST' and 'ISA.' An INST link goes from an individual *I* to a category *C* and asserts that *I* is an instance of *C*. An ISA link goes from category *C* to category *D* and asserts that *C* is a subset of *D*. Implicitly, therefore, if there is a chain of ISA links from *C* to *D*, then it can be inferred that *C* is a subset of *D*. If there is an INST link from *I* to *C* and then a chain of ISA links from *C* to *D*, then it can be inferred that *I* is an instance of *D*. For instance, in Figure 2, it can be inferred that oil paintings are works of art, and that the portrait of Thomas More is a work of art.

The central reasoning mechanism in a semantic network is inheritance: a category and its instances inherit the properties of the categories that contain them. For instance, in Figure 2, the node MorePortrait inherits the Medium arc to Oil from OilPainting, the Form arc to 2D-Image from Painting, and the Depicts arc to Person from Portrait. That is, the system can infer that the portrait of More is a two-dimensional image from the facts that it is a painting, and that all paintings are two-dimensional images.

The advantages of the semantic network architecture are that it is easy and natural to use, its meaning can be defined precisely, and the inheritance mechanism is easy to implement and efficient. The chief drawback is that it is not very expressive. In addition, the apparent simplicity of the representation can end up working against precision; an inexpert user can easily construct a semantic network that looks plausible, but that uses the same notation with two different meanings (Woods, 1975).

The minimal architecture described above is often supplemented with additional features, such as 'meta-arcs' that connect two arcs and describe the logical relations between them (Sowa, 2000). However, the more such features are added, the less simple and natural the representation becomes.

Frame-Based Systems

A frame represents either an individual or a category, and associates with its subject a collection of pairs of a slot with a corresponding filler. A slot is the name of a feature of an individual, and a filler for a slot of an individual is the value of that feature; for example, the Color slot for StatueOf Liberty has filler Green. The filler of a slot for a category contains information about the possible fillers of that slot for individual instances of the category. This can take many different forms; it can be a particular value, a range of values, a constraint on values, or a function that computes the value.

For instance, in frame OilPainting in Figure 3, the value of the Date slot is a constraint asserting that the date of a painting must take place within the painter's lifetime. (The specific syntax used here is invented, but the features are typical of frame-based systems.) As in semantic nets, frames inherit fillers through INST links, which connect an individual to a category, and through ISA links, which connect a subcategory to a supercategory. Other forms of inference in frame-based systems include computing or verifying the value of a slot using inherited procedures or constraints and categorizing a new

```
Frame MorePortrait
  Inst:OilPainting;
  Genre:Portrait;
  Depicts:ThomasMore;
  Shape:Rectangle (29.5 inch, 23.7 inch);
  Surface:Wood;
  Date:1527;
  Painter:Holbein;
  Owner:Frick;
  Image:more.gif {file with displayable image};
EndFrame

Frame OilPainting
  Isa:Painting;
  Medium:Oil;
  Surface: <OR> [Canvas, Wood];
  Date: <CONSTRAINT> [@.Painter.Birth <@.Date ≤ @.Painter.Death];
  Painter: <OR> [ <INSTANCE> Person, <INSTANCE> Workshop];
  Owner: <OR> [Lost, Destroyed, <INSTANCE> Person, <INSTANCE> Institution];
EndFrame
```

Figure 3 Frame-based systems.

individual as an instance of a category based on its features (Minsky, 1975) (Borgida et al., 1989).

Architectures for Large-Scale Systems

Several representational architectures are available for use in large-scale KR. The best known large-scale representational project is CYC, which has been under development since 1984 by a team led by Douglas Lenat (1995). The representation language is called CYCL. CYC is a commercial product, and the system as a whole is proprietary. Although substantial parts, including the structure of CYCL, the upper ontology, and a fraction of the content are openly available, very little has been published about CYC, and scientists outside the project have consistently found it difficult to determine how it can be effectively used, what content it contains, and how it has been evaluated.

Other representational architectures for large-scale systems include KIF (Knowledge Interchange Format) developed at Stanford and KQML (Knowledge Query and Manipulation Language) developed at the University of Maryland. All these contain a central logical component with many extensions of various kinds.

Fundamental Domains

The most difficult problems facing the designer of a knowledge base are those of content: what knowledge is needed for a given application, what concepts are needed, and how can the knowledge be effectively encoded in a given architecture?

KRs for specialized applications generally involve a protracted collaboration between the designers of the knowledge base and the domain experts. The interaction brings to light central concepts, distinctions, and forms of inference in the applications that are not evident to either group at the start (Friedland et al., 2004).

In encoding nonspecialized, commonsense knowledge, a popular methodology is to begin by defining a microworld, a small, coherent domain of study. Aspects of the real world that lie outside the microworld are ignored or dealt with ad hoc. A collection of commonsensically obvious inferences in the microworld is assembled. The researcher constructs a formal model that suffices to justify these inferences, defines symbols to express the concepts used in the inferences, and expresses the knowledge involved in the inferences in terms of these symbols in the selected representational format (Davis, 1990, 1998).

Time

The issues involved in content may be illustrated in a discussion of representations of time, certainly the most ubiquitous domain in automated reasoning.

Ontologically, time may be taken to be discrete or continuous, to be linear or branching, and to consist of points or of intervals. Which choice is made depends on the applications being considered. For instance, in a chess-playing program, it is natural to take time to be discrete, as nothing significant happens between successive states of the board, and to be branching, to express the options available to each player at each stage. In reasoning about physical processes, it is usually desirable to take time to be continuous, in order to describe continuous change, and linear, since no choices are being made. (Uncertainty about the future, as opposed to choices about the future, is easily accommodated in a linear theory of time.)

Many different representations have been devised for time. Some of the most popular include the following:

- *Time stamps*: If a linear model of time is used, and clock times are known precisely and are important, then each event can be marked by date and clock time.
- *Numerical constraints on time*: If a linear model of time is used, and clock times are important but are not fully known, then a reasonable representation can use a collection of symbolic constraints between the times of events, such as 'The date of the painting of More's portrait comes after Holbein's birth and before his death.'
- *The situation calculus*: This theory uses a branching, discrete model of time. There are three primary types of entities: situations, which are essentially instants of time; fluents, which are propositions whose value changes over time, such as 'Obama is President'; and actions, which cause one situation to change to a resultant situation. The two principal symbols are Result(s,a), which maps a situation s and an action a to the situation that results if a is performed in s, and Holds(s,f), the assertion that fluent f holds in situation s (McCarthy and Hayes, 1969).
- *The event/interval calculus*: Another representation for time popular in KR research is based around intervals and events. There are 13 possible temporal relations between intervals; interval i may entirely precede interval j or the end of i may coincide with the beginning of j and so on. The interval language contains primitives to describe these 13 relations, plus the relation Occurs(i,e), meaning event e occurs in interval i (Allen, 1983).
- *Tense logic*: This was developed in the philosophical literature to formalize the tenses of natural language. It is a modal logic, containing operators like 'φ will always be true,' 'φ has been true at some time in the past,' and so on (van Benthem, 1983).
- *Dynamic logic*: This representation is popular in formal theories of programming languages. It uses a discrete, branching model of time. Statements have the form 'after p has been executed, φ will be true', where p is an action or a computer program.

Other Domains

Other commonsense domains that have been extensively studied in the KR literature include the following:

- Spatial reasoning, in particular the development of reasoning systems that can effectively use qualitative information about shape and other spatial relations, rather than requiring exact geometric information.
- Spatiotemporal reasoning, in particular reasoning based on the fact that spatial relations change continuously over time.
- *Physical reasoning*: Here the challenge is to characterize the physical world in the terms in which the human agent encounters it, sometimes called the mesoscopic scale.
- *Mental states of agent*: Knowing, believing, hoping, fearing, and so on. The chief challenge here is to develop a theory

that is precise enough to support useful reasoning but not so idealized as to be entirely unrealistic.
- Communication between agents.

Learning and Knowledge Representation

In view of the immensity of the task of hand encoding a knowledge base of all commonsense knowledge, or even of developing a representation language adequate for such a knowledge base, and in view of the great success that machine learning has had in the past 20 years in many different tasks, the proposal has naturally been made that machine learning techniques be employed to develop both the representation language and the content for a knowledge (Etzioni et al., 2008).

Almost all such recent projects work from texts gathered from the World Wide Web. Projects differ widely in terms of the kinds of information that is gathered:

- The program may have a fixed set of categories and relations and may gather specific instances of these. For instance, the program may know of the category Person and the relation Father, and learn from text that Odysseus was a person and that Odysseus was the father of Telemachus.
- The program may learn both new relations and new instances; for instance, it may learn that Athlete and Team are categories, that Babe Ruth is an athlete, and that PlaysFor is a relation.
- The program may additionally learn semantic relations between categories and relations. For instance, it may learn that Athlete is a subcategory of Person and that PlaysFor is a relation between Athlete and Team.
- The program may learn more complex logical rules or probabilistic correlations, such as, 'If food F is made from ingredient G and G contains chemical C, then F contains chemical C.'

In general, such projects work by building up, side-by-side with the conceptual knowledge base, a collection of linguistic patterns that indicate the target relation and that can be matched against the text. For instance, if a phrase in the text matches the pattern '<*Class*> such as <*Instances*>,' it suggests that the enumerated instances in the text may be examples of the specified category. The accuracy and the coverage of any individual pattern may be low, but if many such patterns are used and are applied over a large corpus of text, the combined evidence may be substantial.

Abstract

Past theories of society, choose to designate, quite properly, those attributes of social relations that are constitutive of the specific nature of that society as identifying labels. Thus, such names as 'capitalist' society or 'industrial' society were created. For the same reasons, the now-emerging form of society represents a 'knowledge' society because the constitutive mechanism or the identity of modern society increasingly is driven by 'knowledge'. Knowledge has become the central economic resource and source of additional economic growth. The article on knowledge society explores the emergence, development, and current state of theorizing about modern societies as knowledge societies.

Past theories of society, choose to designate, quite properly, those attributes of social relations that are constitutive of the specific nature of that society as identifying labels. Thus, such names as 'capitalist' society or 'industrial' society were created. For the same reasons, the now-emerging form of society represents a 'knowledge' society because the constitutive mechanism or the identity of modern society increasingly is driven by 'knowledge'. Knowledge has become the central economic resource and source of additional economic growth (Drucker, [1968]1972: p. 40; Böhme and Stehr, 1986; Stehr, 2002). (I utilize observations about the history of the idea of modern society as a knowledge society first summarized in Stehr (1984). I have added considerable material to the earlier reflections.)

The term knowledge society first appears, as far as I can see, in the name of 'benevolent' societies in England in the nineteenth century. The purpose of one of these societies, the *Provident Knowledge Society* under the patronage of Lord Derby, Lord Shaftesbury, and other distinguished men "is to make regular weekly saving a national habit, and so to increase the facilities for saving that it shall be as easy for a man to put by a small sum as it is now for him to spend that sum in beer or spirits. The Society has published a series of tracts upon *Penny Banks, Pensions, Insuring One's Life*, and other subjects, which are intended to promote thrift and forethought among the working classes; and of these tracts many thousands have been circulated" (The British Medical Journal, 1875: p. 283; also The Scottish Historical Review, 1920). Inasmuch as the benevolent knowledge societies in England saw their mission to enlighten and educate the uninformed public, especially members of the working class, there is at least some resemblance to features of the modern day knowledge societies that also rest on the broad dissemination of knowledge, information and knowledgeability throughout the society.

Early Usages of the Term Knowledge Society

In its contemporary, social scientific version, the term knowledge society and the idea that modern societies are knowledge societies are much more recent. The usage and development of the idea of that *modern society* is a knowledge society date to the early 1970s and more prominently to the 1980s and later.

One of the first social scientists to employ the term 'knowledgeable society' is Robert E. Lane (1966: p. 650). He justifies the use of this concept by pointing to the growing societal relevance of *scientific knowledge* and defines a knowledgeable society, in a 'first approximation', as one in which its members

> (a) inquire into the basis of their beliefs about man, nature, and society; (b) are guided (perhaps unconsciously) by objective standards of veridical truth, and, at the upper levels of education, follow scientific rules of evidence and inference in inquiry; (c) devote considerable resources to this inquiry and thus have a large store of knowledge; (d) collect, organize, and interpret their knowledge in a constant effort to extract further meaning from it for the purposes at hand; (e) employ this knowledge to illuminate (and perhaps modify) their values and goals as well as to advance them. Just as the 'democratic' society has a foundation in governmental and interpersonal relations, and the 'affluent society' a foundation in economics, so the knowledgeable society has its roots in epistemology and the logic of inquiry.

Lane's conception of a knowledgeable society is coupled rather closely to the promise of a particular theory of science and reflects, also, the great optimism or fear, as the case may be, in the early 1960s which suggested that science would somehow allow for the possibility of a society in which common sense would be replaced by scientific reasoning. That is, as Lane stresses in his definition, members of the knowledgeable society are guided in their conduct, if only subconsciously, by the standards of 'veridical truth'.

The very promise Lane attached to scientific knowledge as the motor that would transform modern society into a knowledgeable society is the reason for other social scientists to reflect about the emergence of a 'technical state'. One prominent social scientist who warned about the possibility of a technical state is Helmut Schelsky. Schelsky was one of the most eminent social scientists of the postwar era in Germany. His influence reached well beyond the narrow boundaries of academic social science. His influence was based on the distinctive understanding of the evolution of modern society and the terms he coined to capture core cultural and socio-structural developments. The theories he offered were distinctly middle range and not of a grand design. Lane and Schelsky share in the confidence that scientific knowledge will assume dominance

throughout society and in the case of the political system reduce decision to technical matters. A brief quote from Schelsky ([1961]1965: p. 459) transports the essence of the meaning of the notion of the technical state: "The 'technical state or government' deprives … democracy of its substance. Technical and scientific decisions cannot be subject to democratic decision making, for in this manner they only become ineffective." Helmut Schelsky adds what is perhaps obvious, namely once political decisions are executed based on scientific knowledge alone, the basic premise of democratic participation is eliminated: that is, the assumption that reason and reasoned judgments are equitably distributed throughout society.

Peter Drucker and Daniel Bell's Conceptions of the Knowledge Society

In *The Age of Discontinuity*, Peter Drucker (1968) explicitly and consistently employs the term *knowledge society*. The general thesis places knowledge "as central to our society and as the foundation of economy and social action" (Drucker, [1968] 1992: p. 349). In this most general sense, Drucker's concept of a knowledge society resonates closely with the idea of modern society as a knowledge society, as explicated in subsequent decades. Although Drucker's emphasis of knowledge is, in many ways, pioneering, it is not evident, however, whether he attributes to the knowledge principle, in the late 1960s at least, the same centrality for society as does, for example, at about the same time, Daniel Bell. Nor is there any direct evidence of cross fertilization between Drucker and Bell. Nonetheless, both theorists contributed with their reflections about the rise in the significance of knowledge as an economic resource displacing leading observations about the existence of a *managerial capitalism* immediately after World War II (cf Chandler, 1977; Burnham, 1941).

Drucker goes to considerable and informative lengths to describe some of the novel features and functions of contemporary knowledge. His definition of what counts as knowledge in a knowledge society is not restricted, as is the case for Lane's knowledgeable society, to scientific knowledge. Drucker's account of the emergence of knowledge societies and the knowledge-based economy must be counted among Drucker's original contributions to the theory of the knowledge society. The popular response to the questions about the origins of the knowledge society and the knowledge-based economy typically refers (see Drucker, [1968]1972: p. 279) to the more technically demanding and more complex tasks of jobs. Drucker rejects the 'demand' induced transformation of industrial society and instead points out that "the direct cause of the upgrading of the jobs is … the upgrading of the educational level of the entrant into the labor force." Moreover, Drucker suggests that the stimulus for the increasing demand for knowledge-based work has to do less with changing technological regimes, the growing complexity and specialization of the economy, or enhanced functional steering and coordination needs. The growth of knowledge workers has more to do with the substantial extension in the working life span of individuals and the enhanced knowledge with which individuals come to the labor market in the first place. If we follow Drucker, it is not so much the *demand* for labor and particular skills as the result of more complex and exacting jobs, but a societal transformation that results in the *supply* of highly skilled labor that in turn underlies the transformation of the world of work.

Among the surprising even startling properties of the transformation of the labor market is that the American economy at least was able to "satisfy the expectations of all these people with long years of schooling…. As a result of the change in supply, we now have to create genuine knowledge jobs, whether the work itself demands it or not. For a true knowledge job is the only way to make highly schooled people productive…That the knowledge worker [Drucker first proposed the term knowledge worker in 1959 in his *Landmarks of Tomorrow*] came first and knowledge work second – that indeed knowledge work is still largely to come – is a historical accident. From now on, we can expect increasing emphasis on work based on knowledge, and especially skills based on knowledge" (Drucker, [1968]1972: pp. 285–286; also Drucker, 1992: p. 91).

For a contemporary contrast and comparison between Peter Drucker's notion of the knowledge society and self-organizing knowledge labor as *cognitive capitalism* (cf Boutang, [2007] 2011) and the more recent Italian Marxist inspired analysis of capitalism's cognitive phase (Hardt and Negri, 2000), see Peters and Reveley (2012).

Daniel Bell (1968: p. 198) also employs the term 'knowledge society' in the context of his discussion of the emergence of *postindustrial society*, a designation he ultimately prefers. Bell at times uses the concept knowledge society interchangeably with the notion of 'postindustrial society'. For example, he exclaims at one point in his discussion that "the postindustrial society, it is clear, is a knowledge society" (Bell, 1973: p. 212). The basic justification for such an equivalence is, of course, that 'knowledge is a fundamental resource' of postindustrial society. As a matter of fact, Bell (1973: p. 37) indicates that he could have substituted 'knowledge society' for 'postindustrial society' because either term, and others, for example, 'intellectual society' (Bell, 1964: p. 49), might be just as apt in describing at least some salient aspects of the emerging structure of society that he proposes to examine in his study of the structure and culture of modern society.

Radovan Richta's (1969) theory of the scientific-technical revolution constitutes the socialist counterpart to Bell's theory of society. Bell (1973: p. 212) argues that postindustrial society is a knowledge society for two major reasons: (1) "the sources of innovation are increasingly derivative from research and development (and more directly, there is a new relation between science and technology because of the centrality of theoretical knowledge)", and (2) "the weight of the society – measured by a larger proportion of gross national product and a larger share of employment – is increasingly in the knowledge field." The pace and scale of the translation of knowledge into technology provides the basis for the possibility of modernity. Thus, if there is a "radical gap between the present and the past, it lies in the nature of technology and the ways it has transformed social relations and our ways of looking at the world" (Bell, 1968: p. 174).

Daniel Bell's theory of postindustrial society, Radovan Richta's theory of scientific technological revolution, Helmut Schelsky's ([1961]1965) theory of scientific civilization, or John K. Galbraith's (1967) theory of the new industrial state,

adopt quite readily those principles of theory construction characteristic of classical (sociological) theories of society. Among such principles is not merely a considerable aura of optimism about the future, and the conviction that there is a radical, even revolutionary, break in social relations but often also rather deterministic, law like assumptions about the tempo, the course and the direction of social transformations.

What is evident in both Peter Drucker's and Daniel Bell's designation of modern society as knowledge societies is their common assumption that the significant transformations that bring about new constitutive principles of social relations and hence a new societal configuration are changes within the economic system that then radiate throughout society and affirm the dominance of the economy. As a result, the emergence of knowledge or postindustrial societies out of industrial societies has not undermined in the eyes of Drucker and Bell, the preeminence of the economy. In the course of further reflections about knowledge societies, hypotheses about a reversal of the equation of sub- (i.e., the material foundations) to superstructure (the cultural or cognitive foundations) become a primary research agenda.

From the late 1970s onward, the analysis of the modern society as knowledge societies became more sophisticated looking both backward to the existence of past knowledge societies as well as forward in time toward major social transformations of contemporary society (Böhme and Stehr, 1986). The theory of the knowledge society was developed alongside and competed with theories of modern society such as the *information society*, the *risk society* or the *network society*.

What justifies the designation of the emerging society as a knowledge society rather than, as is at times the case, a science society (e.g., Kreibich, 1986), an information society (e.g., Nora and Minc, 1980), a network society (Castells, 1996; Schiller, 1999), a postindustrial society (Bell, 1964), or as technological civilization (Richta et al., 1969)? A number of reasons are relevant for the choice of the term. Much of the discussion about the information society is animated by a concern with the "production, processing, and transmission of a very large amount of data about all sorts of matter – individual and national, social and commercial, economic and military" (Schiller, 1981: p. 25). But every society has to transmit information. Less, or very little, is said about the genesis of the substance of information, the media of communication, especially human ones, or the reasons for the demand for, and changes brought about by, the contents of the information, which is communicated. Nor are discussions about the information society usually concerned with questions of solidarity or domination in modern society and whether any economic effects of this spread of information and communication technologies cannot just as well be accommodated within more conventional economic discourse, namely "as phenomena best understandable in terms of long-established and familiar market-based criteria" (Schiller, 1981: p. xii). The category 'postindustrial society' is misleading because 'industry' or manufacturing does not vanish in modern societies. True, industry is transformed, it is host to many fewer jobs but it is misleading to think that it will disappear. The contribution of the manufacturing sector in terms of the value generated remains unchanged.

Mature Theories of the Knowledge Society and Its Antecedents

The historical emergence of 'knowledge societies' does not occur suddenly; it represents not a revolutionary development, but rather a gradual process during which the defining characteristic of society changes and a new one emerges. Even today, the demise of societies often is as slow as is their beginning. Social transformations rarely occur in spectacular leaps. Nonetheless, proximity to significant social, economic, and cultural changes seems to assure that what comes into view appears to be particularly significant and exceptional. The disruption of routines displaces orientations but it remains "difficult to pinpoint the actual crystallization of a new state of affairs so as to identify, both clearly and unequivocally, the emergence of a new society and its new modes of behavior" (Narr, [1979]1985: p. 32).

Knowledge societies do not come about as the result of a simple unimodal unfolding and in an unambiguous fashion. Knowledge societies do not turn into some kind of one-dimensional social figurations. Knowledge societies become similar by remaining or even becoming dissimilar. New technological modes of communication and transportation break down the distance between groups and individuals but the isolation between regions, cities, and villages remains. The world opens up and creeds, styles and commodities mingle, yet the walls between convictions of what is sacred do not come tumbling down. The meaning of time and place erodes while boundaries are celebrated.

Modern society was, until recently, conceived primarily in terms of property and labor. Labor and property (capital) have had a long association in social, economic, and political theory. Work is seen as property and as a source of emerging property. In the Marxist tradition, capital is objectified, encapsulated labor. On the basis of these attributes, individuals and groups were able or constrained to define their membership in society. In the wake of their declining importance in the productive process, especially in the sense of their conventional economic attributes and manifestations, for example as 'corporeal' property such as land and manual work, the social constructs of labor and property themselves are changing. While these features of labor and property certainly have not disappeared entirely, a new principle, 'knowledge', has been added which, to an extent, challenges as well as transforms property and labor as the constitutive mechanisms of society.

The foundations of economic growth or the "wealth-creating activities will be neither the allocation of capital to productive uses nor 'labor' – the two poles of nineteenth- and twentieth century economic theories … The representative social groups will be neither the 'capitalist' nor the 'worker' … The ruling group will be the knowledge workers, knowledge executives, knowledge professionals, and knowledge entrepreneurs" (Drucker, 1992: p. 94; also Stehr, 1992, 2002; Grundmann and Stehr, 2012).

Dating Modern Knowledge Societies

Radovan Richta et al. (1969: p. 276) date the beginning of the profound transformation of modern society, through the

scientific and technological revolution, from the 1950s. Daniel Bell (1973: p. 346) argues, even though he points out that it really is foolhardy to give precise dates to social processes, that the 'symbolic' onset of the postindustrial society can be traced to the period since the end of World War II, for it was during this era that a new consciousness about time and social change began to emerge. In contrast, Block and Hirschhorn (1979: p. 368), who ask about the beginning of the emergence of the new productive forces typical for postindustrial society, namely, knowledge, science, and technology, and in particular the period when they began to make a decisive difference in production, reach the conclusion that the 1920s already saw such a qualitative shift occurring. In the 1920s, at least in the United States, the input of labor, time, and capital were constant or had begun to decrease while output had begun to rise. In economic terms therefore, knowledge has become the crucial source of (added) value.

Of course knowledge has always had a function in social life; as a matter of fact, one could speak justifiably of an anthropological constant: human action is knowledge based. Social *groups* and social roles of all types depend on, and are mediated by, knowledge. Relations among *individuals* are based on knowledge of each other. Similarly, power has frequently been based on advantages in knowledge, not only on physical strength. And, last but not least, societal reproduction is not merely physical reproduction but, in the case of humans, always cultural, i.e., reproduction of knowledge. In short, knowledge is not confined to a particular social system (cf Luhmann, 1990: p. 147). In retrospect, one is able to describe a variety of ancient societies as knowledge societies, for example, ancient Israel, which was a society structured by its religious law like Tora-knowledge. Ancient Egypt was a society in which religious, astronomical, and agrarian knowledge served as the organizing principle and the basis of authority.

Contemporary society may be described as a knowledge society based on the penetration of all its spheres of life by knowledge. As a matter of fact, knowledge is not coupled to a particular social system. Marxist theories of society have always assigned decisive importance to the forces or means of production for societal development since "man's understanding of nature and his mastery over it by virtue of his presence as a social body … appears as the great foundation-stone (*Grundpfeiler*) of production and of wealth", so that general knowledge becomes a direct force of production (Marx, [1939–1941]1973: p. 705). Contemporary Marxist theories, especially through the notion of the Scientific-Technological Revolution developed by Radovan Richta and others, have analyzed scientific and technical knowledge as the principal motor of change. Max Weber's seminal inquiry into the unique features of Western civilization stresses the pervasive use of reason to secure the methodical efficiency of social action. The source of rational action and, therefore, of rationalization is found in particular intellectual devices. The theory of industrial society, as developed by Raymond Aron (1962), which encompasses both socialist and capitalist forms of economic organization, stresses first and foremost the extent to which science and technology shape the social organization of productive activities and, therefore, other forms of life in society. More recent theories of postindustrial society and similar efforts at forecasting the course of social evolution of industrial society, in particular those by Daniel Bell, have elevated, as we have seen, theoretical knowledge as the axial principle of society.

The Restrictive Concept of Knowledge

Knowledge represents a capacity to act (see Stehr, 1984). The knowledge referred to in many of the early theories of the knowledge society, and the groups of individuals that acquire influence and control with it, are conceptualized narrowly. Paradoxically perhaps, there is a tendency to overestimate the efficacy of 'objective' technical-scientific or formal knowledge and the immediate 'performative' capacity of knowledge. The initial theories of modern society that evolve into the theory of the knowledge society lacked sufficient detail and scope in their conceptualization of the 'knowledge' supplied, the reasons for the demand of more and more knowledge, the ways in which knowledge travels, the rapidly expanding groups of individuals in society who, in one of many ways, live off knowledge, the many forms of knowledge that are considered as pragmatically useful, failed to distinguish between information and knowledge, the application of knowledge to knowledge, the commodification of knowledge and the various effects which knowledge may have on social relations. Peter Drucker's (1993: pp. 52–53) idea that there has been "a radical change in the meaning of knowledge" is illuminating: "In both West and Asia knowledge had always been seen as applying to *being*. Almost overnight it came to be applied to *doing* (my emphasis)."

Contemporary theories of knowledge societies advocate a conception of scientific knowledge that is distant to any notion associated with technological or scientific determinism, especially the one-sided or unidirectional forms of determinism. The constraining features of science and technology are, however, by no means underestimated. But in contradistinction to most arguments in favor of technological and scientific determinism, and the theories of society associated with such views, the crucial point about knowledge societies is that science and technology have simultaneously strong features that allow for resistance to homogeneous transformation (Stehr, 2013). That is, science and technology have important enabling features that increase the number of available strategies, heighten flexibility or affect the ability of the powerful to exercise control and constraining forces that limit choices, reduce options and enhance the fragility of major social institutions, and limit the 'power' of knowledge and impose penalties and risks (e.g., Stehr, 2001). It is therefore by no means contradictory to maintain that knowledge societies can simultaneously become more standardized and more fragile. Generally, it is important to avoid overstating the extent to which science and technology are forces that merely are means of control and regulation and therefore constrain human agency and limit social action. They do, but that is only part of their consequences. The other part is represented by the 'opposite' because science and technology enter relational fields of social action and can assume quite different values or outcomes especially for opposing social forces and purposes.

The Economic System of the Knowledge Society

The emergence of knowledge societies signals first and foremost a radical transformation in the *structure of the economy*. Productive processes in *industrial society* are governed by a number of factors, which appear to be on the decline in their significance as conditions for the possibility of a changing, particularly growing economy. The common denominator of the changes in the structure of the economy seems to be a shift from an economy driven and governed, in large measure, by 'material' inputs into the productive process and its organization to an economy in which transformations in productive and distributive processes are determined much more by 'symbolic' or knowledge-based inputs.

The economy of industrial society is initially and primarily a *material economy* and then changes gradually to a monetary economy; for example, Keynes' economic theory, particularly his *General Theory* (1936), reflects this transformation of the economy of industrial society into an economy affected to a considerable extent by monetary matters. But as more recent evidence indicates, the economy Keynes described now becomes a (nonmonetary) *symbolic economy* (cf Drucker, 1980: p. 8). The changes in the structure of the economy and its dynamics are increasingly a reflection of the fact that *knowledge* becomes the leading dimension in the productive process, the primary condition for its expansion and for a change in the limits to economic growth in the developed world. In the knowledge society, most of the wealth of a company is increasingly embodied in its creativity and knowledge. With the exception of the most standardized commodities and services, factors other than "the amount of labor time or the amount of physical capital become increasingly central" (Block, 1985: p. 95) to the economy of advanced societies (see especially Drucker, 1986; Lipsey, 1992).

One of the few extensive and early empirical contributions to the analysis of the nature and the emergence of a knowledge society and the knowledge-based economy (knowledge industry) in particular more than five decades ago may be found in the work of the economist Fritz Machlup (1962, 1981; 1984). His analysis is constituted by an elaborate apparatus of empirical, often census type information about observable shifts and trends, such as in the occupational structure, intended to show that a knowledge society is indeed emerging and can therefore be documented in its own self-exemplifying terms, that is, in a quantitative (rational) manner. The most recent data generated as part of the Machlup research programme to quantify the overall expenditures for knowledge production in the United States may be found in Rubin and Huber's (1986) study. Their attempt to measure knowledge incomes and expenditures connected with commodities and services constitutes the explicit effort to extend Fritz Machlup's (1962) investigation into the proportion of the Domestic Economic Product that goes to knowledge production.

The Nature of Knowledge Societies

Advanced theories of the knowledge society do not argue that knowledge societies become uniform social and intellectual entities. They allow, for example, for the coexistence, even interdependence, of historically distinct forms of social organization and thought. Knowledge societies do not spell the end of ideology or irrationality. Nor is scientific knowledge, as a cultural ensemble, merely a way of deciphering the world; it is also a model for the world (capacity to act).

However, in order to demonstrate and appreciate fully the significance of knowledge for societies and social action generally, and for advanced societies in particular, one first has to formulate a sociological concept of knowledge. One must be able to differentiate between what is known, the content of knowledge, and knowing itself. What is it, then, that we know? Some examples taken from the *Oxford Dictionary of Current English* indicate the following instances: "Every child knows that two and two make four. He knows a lot of English. Do you know how to play chess? I don't know whether he is here or not." These examples show that knowing is a relation to things and facts, but also to laws and rules. In any case, knowing is some sort of participation: knowing things, facts, and rules is 'appropriating' them in some manner, including them into our field of orientation and competence. A very important point, however, is that knowledge can be objectified, that is, the intellectual appropriation of things, facts, and rules can be established symbolically, so that in the future in order to know, it is no longer necessary to get into contact with the things themselves but only with their symbolic representations. This is the social significance of language, writing, printing, and data storage. Modern societies have made dramatic advances in the intellectual appropriation of nature and society. There is an immense stock of objectified knowledge that mediates our relation to nature and to ourselves. In a general sense, this advancement has been called, in other contexts, modernization or rationalization. This secondary nature is overgrowing the primary nature of humans. The real and the fictional merge and become indistinguishable; theories become facts and not vice versa, that is, facts do not police theories.

It is only after one acquires a sense of the societal significance of such opposites and oppositions that the full sociological significance of knowledge begins to emerge. Such a perspective assures that one realizes the extent to which knowledge can form the basis for authority, that access to knowledge becomes a major societal resource and the occasion for political and social struggles.

Applied to contemporary society, the question becomes whether knowledge can provide the robust principle for social hierarchies and stratification, for the formation of inequality structures, for the distribution of chances of social and political influence, and for the nature of personal life and, finally, whether knowledge may also prove to be a normative principle of social cohesion and integration even though the variations and alterations in the reproduction of knowledge appear to be enormous. Paradoxically, efforts to entrench necessity in history or eliminate chance from history have produced, at least at the collective level, it seems, its opposite. The role of chance at the collective level continues to be part of the way society comes to be organized. Knowledge societies are (to adopt a phrase coined by Adam Ferguson) the result of human action but not necessarily of deliberate human design. Knowledge societies emerge as adaptations to persistent but evolving needs and changing circumstances of human conduct.

Among the most significant transformations in circumstances that face human conduct is the continuous 'enlargement' of human action.

Abstract

This article examines the history and the development of the sociology of knowledge, the subfield of sociology focused on the relationship between the processes and products of human cognition (including ideas, ideologies, scientific theories, religious, philosophical and political doctrines, moral beliefs, mental categories, cultural and organizational discourses, and the forms and practices of everyday knowing) and their sociocultural origins and consequences. Sociological examination of this relationship has involved linking intellectual products and processes to factors such as sociohistorical contexts, material and cultural conditions, modes of production, power relationships, institutional arrangements, internal organizational processes, and various social positions and interests.

Most inquiries comprehended under the classification of sociology of knowledge as an academic field were familiar long before the term was devised. They have to do with the circumstances that foster – or hamper – the acquisition and reproduction of knowledge and with the circumstances that account for intellectual designs taken or offered as true, notwithstanding the absence of philosophically adequate warrant for such claims. The issues arise in various forms throughout the philosophical canon, hedging about the borders of knowledge by excluding categories of beliefs whose status is seen as a function of factors unrelated to epistemological grounds.

This article examines the history and the development of the sociology of knowledge, the subfield of sociology focused on the relationship between the processes and products of human cognition (including ideas, ideologies, scientific theories, religious, philosophical and political doctrines, moral beliefs, mental categories, cultural and organizational discourses, and the forms and practices of everyday knowing) and their sociocultural origins and consequences. Sociological examination of this relationship has involved linking intellectual products and processes to factors such as sociohistorical contexts, material and cultural conditions, modes of production, power relationships, institutional arrangements, internal organizational processes, and various social positions and interests.

The stages identified in the development of the sociology of knowledge are, first, the long period from antiquity to the early twentieth century, during which thinkers moved from frequent general claims about the social bases and effects of various types of ideas to more specific causal statements, seen in Marx's analysis of the material foundations of ideology and in Durkheim's studies of the social origins of the categories of human thought; second, the period from the early 1920s to the early 1960s, when the sociology of knowledge emerged as a distinct theory-and-research subfield, initially in the writings of Karl Mannheim and Max Scheler, which accented its epistemological and political implications, and then in the more research-oriented work of R.K. Merton and others; third, the period to the present, during which the sociology of knowledge, after an initial decline, has undergone a revival and has been pulled in contrary directions by various agendas.

The sociology of knowledge is a summative term for an assortment of theoretical statements and empirical studies that deal with the relationship between different processes and products of human cognition and other sociocultural factors. On the organizational map of the discipline of sociology in Europe and in North America, the sociology of knowledge has generally occupied a marginal position, with its warrant and scope so contested that it may be argued "that the history of the subdiscipline … has been the history of its various definitions" (Berger and Luckmann, 1966: p. 4). Focusing on manifestations of knowledge that include ideas, ideologies, scientific theories, religious and political doctrines, moral, ethical and philosophical beliefs, world-views, mental categories, cultural and organizational discourses, languages, social norms, and the forms and practices of everyday knowing, sociologists of knowledge (whether self-identified or retrospectively claimed for the area by later contributors) have concerned themselves with the sociocultural consequences of this range of intellectual products and processes and, particularly, with their origins and transformations – developments that have been linked to sociohistorical contexts, material and cultural conditions, modes of production, power relationships in various forms, institutional arrangements, internal organizational processes, and a vast array of different social positions and interests. Sociologically relevant reflection on this set of issues may be periodized in three broad stages.

Antecedents of the Sociology of Knowledge

While observations about the social foundations and consequences of various cognitive products and processes have a complex history that extends back to the Greeks and forward through such Renaissance figures as Machiavelli and Francis Bacon, the modern roots of the sociology of knowledge are generally dated from the French and Scottish Enlightenment of the eighteenth century, when thinkers like Helvetius, Holbach, and Voltaire turned attention to the social bases and effects of religious – as contrasted with scientific – conceptions, while Montesquieu, Rousseau, and Condorcet adumbrated the broader thesis that human consciousness is socially

determined. Working in this tradition, Destutt de Tracy advocated a 'science of ideas' that would trace human thoughts to their sensory and material conditions, ultimately making possible the construction of a new morality and a perfected political order. For this science, he coined the term 'ideology' (in 1796) – a neologism that his critics swiftly converted into a pejorative word for doctrinaire dreams and illusions (Eagleton, 1991; Kennedy, 1978; Larrain, 1979).

Francis Bacon was stringently ascetic in his determination of what counts as scientific knowledge, but he also put his faith in the civil history that was supposed to guide statesmen; the eighteenth-century Scottish moral philosopher, Adam Ferguson, developed his distinction between the 'history of the individual' that grounded scientific knowledge and the 'history of the species' that featured the stages of history and other synthetic conceptions that made him interesting to later commentators. In John Stuart Mill's *Logic of the Moral Sciences* (1843) there is a succession of chapters on the 'physical' and on the 'historical' sciences. Notwithstanding Mill's ingenious designation of the latter as representing the 'inverse deductive' method, there is little doubt that he did not consider the latter kinds of theory – exemplified by Saint-Simon and Comte – to be 'scientific' in the strict sense that governs his entire treatise, although he clearly finds such theory relevant to social understanding.

In the early nineteenth century, Auguste Comte declared the evolution of modes of human thought the main topic of the new discipline of sociology, erecting the field on the Law of Three Stages, viz., the assertion "that each of our leading conceptions – each branch of our knowledge – passes successively through three different theoretical conditions: the theological or fictitious; the metaphysical, or abstract; and the scientific, or positive" (1975[1830]: p. 71). Substituting French positivism for German idealism, G.W.F. Hegel (1967[1807]) likewise presented the history of society as a sequence of intellectual stages – as successively developing forms of human consciousness, dialectically progressing to a condition of absolute (genuinely scientific) knowledge.

French and Scottish Enlightenment philosophy recognized that all social differences have social causes and are thus potentially subject to human control. Social, economic, and political factors determine the genesis, structure, and content of human consciousness. Hence the philosophers of the Enlightenment anticipated what became a major thrust of the sociology of knowledge. In the main, however, philosophers have tried to show that such a sociology is neither possible nor desirable. Immanuel Kant allowed that perception always involves categories of understanding and concepts, but he viewed the understanding itself as a priori. Empiricists of the most widely varied persuasions have argued that (scientific) knowledge is warranted by direct experience not dependent on social conditions. At best, nontheoretical factors might influence the genesis of ideas, but not the structure and content of thought itself.

From the mid-nineteenth to the early twentieth century, early modern anticipations of the sociology of the knowledge were elaborated in many directions, particularly in connection with the development of 'classical' sociological theory. Rejecting Hegelian idealism for historical materialism, Karl Marx conceptualized the connections between human thought and social conditions in several ways. In his most encompassing formulation, he asserted that dialectically changing "modes of production [formed] the basis of all history" and that the "origins and growth [of] all the different theoretical products and forms of consciousness, religion, philosophy, ethics, etc., etc." – the idealistic superstructure – were explainable 'from that basis' (Marx and Engels, [1846]1970: pp. 57–58). Taking the social relations of production as 'the realm of real history,' Marx's early work cast this superstructure as the derivative 'realm of ideology,' using the latter term in the pejorative sense of 'illusions' and distorted 'inversions' of reality that 'veil the class struggle' and thus promote existing patterns of class domination (Marx and Engels, [1846]1970: pp. 47, 119; Marx, [1852]1963: pp. 46–47). Marx also linked particular ideas to specific 'material interests' and held that "the class which has the means of material production at its disposal has control … over the means of mental production," so that "the ideas of the ruling class are in every epoch the ruling ideas," as these are developed by 'conceptive ideologists' perfecting the illusions that benefit their class (Marx and Engels, [1846]1970: pp. 64, 65, 99). Marx's later work, in contrast, presented ideology less as a superstructural inversion of reality than as a reflection of inversions already embedded in particular modes of production. Characterizing capitalism itself, for example, as an 'enchanted and perverted world,' he held that, whatever their class interests, conceptualizers under capitalism generally 'remain more or less in the grip of the world of illusion,' a world that 'corresponds' with "the forms of illusion in which they move about and find their daily occupations" ([1894]1967: pp. 827–831; for discussion, see Eagleton, 1991; Mepham, 1979). Subsequently, many of Marx's followers overlaid this negative view of the social functions of ideology with a broader "sense of ideology as the mental forms within which men and women fight out their social conflicts" (Eagleton, 1991: p. 90). This is a tendency evident in the work of Bernstein, Lenin, and Lukács, and in Hoare and Smith's conception of ideologies as forces that, under sociohistorical conditions that can "organize human masses, and create the terrain on which men move, acquire consciousness of their positions, struggle, etc" ([1948–51] 1971: p. 377).

Emile Durkheim is also a forerunner of the sociology of knowledge, although he did not fully succeed in offering a comprehensive model of the process of classification he sought to present. Coming from the French tradition, Durkheim approached knowledge from a different angle. Extending his concern with the social bases (and functions) of such 'collective representations' as religion and morals to the 'extralogical origin' of 'logical thought,' Durkheim argued that the 'mental operations' by which members of preliterate societies "classify … things, events, and facts about the world into kinds and species [are] modeled on [their] form of social organization," i.e., that "the first logical categories were social categories; the first classes of things were classes of men, into which these things were integrated" (Durkheim and Mauss, [1903]1963: pp. 3, 4, 8, 82). Generalizing the point, Durkheim subsequently proposed that the form and the content of all the 'categories of human thought' – of the most basic 'conception[s] of time, space, cause, number, and so on,' even in their modern scientific incarnations – "depend on the way in

which the collectivity is organized, upon its morphology, its religious, moral, and economic institutions, and so on" ([1912]1995: pp. 14–16). Controversial to this day, the claim proved widely influential, inspiring work by Halbwachs (1925), Granet (1934), and others. Durkheim and Mauss, by researching the classification processes of preliterate societies, reached the conviction that all important categories of human thought are socially conditioned. Their thesis that the classification of things reproduces the classification of people (e.g., into clans) is often still the starting point for sociological research.

The Sociology of Knowledge as a Specialty Area

In the 1920s the decisive impulses for the emergence of the sociology of knowledge as a theory-and-research area with its own name came from Max Scheler (1874–1928) and Karl Mannheim (1893–1947). Their separate efforts led to the creation of *Wissenssoziologie* as a symptomatic product of a deep-rooted crisis in the social and historical consciousness of Weimar Germany, where historicism, relativism, and skepticism were vigorously debated (Meja and Stehr, 1982, 2014). What was often a naïve belief in progress came under attack by distrust and skepticism. The sociology of knowledge evolved in this situation as the doctrine of the rise and fall of social processes, relations, and depictions proper to the cultural sphere of knowledge (Scheler), and especially the doctrine of the link between knowledge (or thought) and the social context within which it occurs (Mannheim). In contrast to the Marxist critique of ideology, the sociology of knowledge lays less emphasis on the concealing intention of assertions than on the varied structures of consciousness possessed by the different subject types in history and society.

Even though Karl Mannheim is widely seen as the main founder of the sociology of knowledge, it was Max Scheler who coined the term 'Wissenssoziologie,' as an extension of his interests in philosophy. Scheler's efforts generated a research program in the sociology of culture – and especially the sociology of knowledge – that was by no means constrained within the limits of the philosophical context he postulated. Seeking to recognize "the social–historical development of [even] the highest types of human knowledge" but to "escape [from the] philosophical relativism" that had led contemporaries to deny the truth-claims of ideas "conditioned by a historical and sociological standpoint," he challenged Marx's thesis that one "can 'explain' th[e] ideal world from the world of real history" by asserting that "the history of real factors" – understood as a sequence in which kinship, political, and finally economic factors successively hold centrality – "does not at all determine the positive meaning-content of works of mind, though it does hinder, release, delay, or hasten [their] development," opening and closing "the sluices of the spiritual stream" ([1924]1980: pp. 41–42, 53–54; see also Frisby, 1983).

Mannheim's ambitious program was to lay the foundation for a sociological analysis of knowledge (Meja and Stehr, 1999). Like Scheler, he took a broader view of the Marxist concept of superstructure and argued that psychological, biological, intellectual and religious factors, as well as the purely economic, lay behind it. Investigating the social conditions of the various forms of knowledge, he excluded mathematics and portions of the 'exact sciences' from his analysis, seeking to problematize the 'social conditioning' of the forms and contents of 'every product of thought' – 'perceptions and interpretations,' moral concepts of 'duty, transgression, and sin,' political 'opinions, statements, [and] propositions,' and the total 'modes of thought' of different epochs, cultures, and social groups (see Pels, 1996). According to Mannheim, such thought-products stand in 'multiple interconnections' with 'the structure of historical reality,' with 'the social position of given groups' – a phrase primarily denoting not only class position, but also including "generations, status groups, sects, occupational groups, schools, etc." – and with "the historical–social situation of the intellectually active and responsible members of the group" ([1929]1936a: pp. 56–57, 81–82, 86; [1929]1936c: pp. 264–265, 276). In putting forth this view, Mannheim hoped to lay the foundation for a wide-ranging academic field that would subject "the relationship between thought and existence" to systematic 'empirical research' ([1929]1936a: p. 69; [1929]1936c: p. 264; see also 1936b), and he engaged in such research of himself, most notably in his study on the problem of generations ([1928]1952a), on economic ambition ([1930]1952a), competition ([1928]a), structures of thinking ([1922–24]1982a) and similar topics in the sociology of culture, as well as his later work in political sociology, notably on the theme of planning ([1935]1940). Above all, Mannheim is known for his methodological and substantive work, beginning with his seminal essay on German conservative thought ([1925]1986; see Kettler et al., 1984). Mannheim's most famous book is *Ideology and Utopia* ([1929]1936a; Kettler et al., 1984), in which he elevated the concept of 'ideology,' despite its reductionist and polemical associations, to a central place in the interpretation of all modes of knowledge. Mannheim set for the sociology of knowledge a large agenda, borne from his belief that examination of "the relationship between the intellectual positions held and the social position occupied" would necessarily reveal that 'every point of view' – Marxism included – 'is particular to a social situation.' From this it followed, for Mannheim, that "the thought of all parties in all epochs is of an ideological character," where he took 'ideological' to mean 'narrow' and 'one-sided' – properties with important epistemological and political implications. By exposing the one-sidedness of all perspectives, the sociology of knowledge would make possible 'a new type of objectivity,' a dynamic synthesis of different viewpoints that would bring political rivals into dialogue, checking their pernicious tendency to unmask each another's ideas as mere illusions (1936a: pp. 77–85; [1929]1936b: p. 5; see also Elias, 1971; Kettler and Meja, 1995; Kettler et al., 2008).

Ideology and Utopia opens with a discussion of the crisis in politics caused by all parties now making use of the device once reserved to the Marxists. Each unmasks the positions advanced by the others as nothing but interest-bound ideology, so that none can retain any confidence in the objectivity of even their own perceptions and claims, This is the impasse that the sociology of knowledge will help overcome, in part by reassuring each and all parties about

the perspectival character of all political knowledge. The intervention is meant to foster exchanges between the parties that lead to mediation, although these exchanges can only approximate the 'free exchange of ideas' projected by liberalism. In his discussion and critique of the socialist–communist conception of the theory–practice relationship, for example, Mannheim characterizes a process wherein actors representing 'real' social factors mutually take one another's measure and cumulatively create a sequence of 'real' situations that sequentially provide the starting point for the next phase of development. Quite apart from Marxism, Mannheim contends, we know at least since Carl Schmitt that this is a more adequate account of parliamentary political institutions than the liberal one. Schmitt clearly exposed the liberal illusion of parliaments as societies for the discovery of truth through discussion. The Marxist version of this 'real' contestation, he points out, envisions a moment of revolutionary overturn, when all contradictions are dialectically overcome. As his analysis proceeds, however, leaving the exposition of the different ideological standpoints behind, it becomes clear that his culminating conception of a politics that has been brought beyond critical impasse through the intervention of the sociology of knowledge amounts to a regularization of that 'real' process, without the dramatic disruptions and presumed transcendent reconciliations achieved, according to Marxists, by the anticipated revolutionary overturn.

The sociology of knowledge dispute, even while lasting only a few years, until Hitler's rise to power, focused upon the most important methodological and epistemological confronting German sociology in the Weimar period. While the more-than-30 major papers published in response to Mannheim's book (Meja and Stehr, 1982, [1990]2014) cover a considerable range of theoretical positions, the majority of responses and critiques come from Marxist or socialist scholars of various orientations, among them the orthodox Marxists Karl Wittfogel, Otto Neurath, and Albert Fogarasi; the anti-positivist Marxists Max Horkheimer, Herbert Marcuse, and Ernst Lewalter; the religious socialist Paul Tillich; and the Social Democrats Hannah Arendt, Guenther Stern (later Guenther Anders), and Hans Speier. The interest in the relationship between Marxism and the sociology of knowledge constitutes the major point of unity in the response to Mannheim's book. The positions range from seeing in the sociology of knowledge a sophisticated reformulation of the materialist conception of history to attributing its popularity to a neutering and betrayal of Marxism.

Mannheim thought that the sociology of knowledge could play a key role in intellectual and political life by showing that social conditions help to give rise to political philosophies, ideologies, cultural achievements, and competing systems of thought, thereby introducing reason into politics. His agenda drew broad attention to the sociology of knowledge in Europe and in America and set the new field on an unsteady course. In Europe, his epistemological and political views became the focus of extensive critical discussion and made the field, for decades, largely a site of *meta*-theoretical controversy (Frisby, 1983; Wolff, 1993; Meja and Stehr, 1988). In America, where engagement with sociology-of-knowledge type issues had long been underway (Fuhrman, 1980), Mannheim's call for empirical studies had greater resonance and fueled efforts to constitute the sociology of knowledge as a specialized subdiscipline dedicated to 'fruitful empirical research,' rather than to debate over 'philosophical' questions of relativism, objectivity, and the like (quoting Wirth, 1936: pp. xxi, xxvii; see also Kettler and Meja, 1995: pp. 193–246; see also Kettler et al., 2008).

Particularly significant here are Robert K. Merton's writings in the early 1940s, which sought to move the sociology of knowledge from 'speculative insight' to 'rigorous test,' by purging Mannheim's ideas of "their epistemological impedimenta" and associating the field with a defined "list of problems [open to] empirical investigation" ([1945]1968a: p. 562; [1941]1968b: p. 542). To this end, Merton elaborated a "paradigm for the sociology of knowledge," in which he replaced Mannheim's "amorphous category of knowledge" with a systematic inventory of different types and aspects of 'mental productions' and then differentiated the many possible sociocultural or 'existential bases' for human thought-products ([1941]1968a: p. 552; 1968b: pp. 514–515). Most distinctively, Merton gave prominence to the question (which he faulted his predecessors for neglecting) "*how* are mental production related to the existential basis?" – distinguishing, in reply, a wide range of possible modes of relationship, analysis of which "promise [d] to take research in the sociology of knowledge from the plane of general imputation to that of testable empirical inquiry" ([1945]1968b: pp. 515, 537).

This promise proved difficult to realize, however. In the course of the next 20 years, students of Merton occasionally took up the challenge – Gouldner (1965) with research on Plato's social theory as a response to the social tensions present in ancient Greece, Coser (1965) with work on the general societal and institutional conditions that favored the development of Western intellectuals. These studies joined writings by Mills ([1943]1964) on the social roots of American pragmatism (see also Mills, 1963), by Znaniecki (1940) and Shils ([1955–68] 1972) on intellectuals, by members of the Frankfurt school on the ideology of capitalist societies (see especially Marcuse, 1964), and by a scattering of other scholars on a miscellany of topics (see the collection by Curtis and Petras, 1970) to steer the sociology of knowledge in more empirical directions. But these remained sporadic efforts, intermixed with works offering programmatic definitions of the sociology of knowledge and further discussion of Mannheim's more philosophical concerns (see, e.g., DeGré, [1939–43]1985; Stark, 1958.

Kurt H. Wolff (Mannheim's student in Frankfurt, his translator and editor in America, and – though not a disciple – loyal to Mannheim and the sociology of knowledge project even in exile) is an interesting and central figure here (Wolff, 1959, 1968, 1974, 1976, 1983, 1993; see also Backhaus and Psathas, 2007). Mannheim's belief was that the crisis of universal distrust can only be countered by radical doubt, and that this doubt will paradoxically eventuate in a new ontology and in a new foundational science of being. From this point of view, sociology of knowledge is not a positive discipline with consequences for methodology: it is philosophy carried on by more appropriate means. This is the motif to which Kurt H. Wolff's mediation has sought to give expression, life, and relevance. Hardly accessible to

'insiders' of 'American sociology,' this motif may nevertheless be audible in a sociological profession that has been adopted as home by many students deeply troubled by a new sense of social crisis and by a corresponding disbelief in the methodological asceticism of empirical inquiry. Mannheim's questions are seen by Wolff to revolve around Nietzsche's ghastly discoveries, now confirmed by the manifest discrediting of all claims to speak with the authority of reason in the spheres of utmost importance to human action. The exposure of such claims as 'rationalization' and 'ideology' itself proceeds by rational means, of course, at first embodied in shrewd political assaults and eventually in the two genealogical inquiries of psychoanalysis and sociology of knowledge.

For Wolff Mannheim's sociology of knowledge epitomizes the courage to reshape and to pursue this destructive course without abandoning the goal of finding a new affirmation. To avoid misunderstanding, it should be emphasized that Wolff was not content to spin out metaphysical suppositions to resolve these gravest of all doubts. He was strict in his understanding of the work that sociologists of knowledge must do, and generous in his appreciation of quite detailed examples of the empirical craft. The point is not to encourage speculation, but to foster reflexive attention to the meanings of the work that sociologists of knowledge professionally do, locating it in the context of purposes that need to be subserved by knowledge and of problems that must be handled wisely. If knowledge is what our sociological analyses show it to be, what is the point of questions that Wolff regarded as central to Mannheim's sociological project and that Wolff asks us to receive as integral to the tradition of inquiry initiated by Mannheim?

Such work as Wolff's distanced empirically oriented sociologists from the field, even as various sociology-of-knowledge type questions resurfaced in the sociology of religion, the sociology of education, the sociology of occupations and professions, the sociology of generations, the sociology of public opinion and mass communication, and the sociology of science (Coser, 1968: p. 432), as well as in research by historians of science and historians of ideas (see especially Ringer, 1969).

The era that began with the writings of Scheler and Mannheim and extended to the mid-1960s remains, nonetheless, the most active and perhaps fruitful period in the sociology of knowledge as a specialty area, and it stamped the field with a set of basic assumptions that were common to most work in the field at the time. These included, first, the assumption of a division between sociocultural factors, on the one side, and the substantive contents of thought-products and processes, on the other, where the former factors were 'external' to the realm of knowledge, while the latter were 'internal'; second, the supposition that the 'internal' factors were easily interpretable by the sociological investigator, their meanings more-or-less transparent in the statements where they were contained; and, third, the belief that sociological explanations of knowledge chiefly involved appeals to 'external' factors at the macrolevel, i.e., to societal-wide economic, political, and cultural developments, or combinations thereof (Camic and Gross, 2000; see also Kuklick, 1983).

Recent Developments

For a variety of reasons, largely exogenous to the area itself, interest in the sociology of knowledge diminished for two decades beginning in the early 1960s. This was due partly to a continuation of the tendency, already evident earlier, for partial incorporation of sociology of knowledge topics into other sociological subfields. Expanding interest in the sociology of science proved especially consequential here, for in the process of focusing on scientists' career patterns and on the organizational and normative conditions that sustain scientific institutions, sociologists of science effectively denied – despite contrary suggestions in the influential work of Kuhn (1962) – that there was even much possibility for a "sociology of the conceptual and theoretical contents of science" and related domains of knowledge (Ben-David, 1971: p. 14). In the face of this challenge, Berger and Luckmann attempted to redirect the sociology of knowledge to the study of "what is taken for granted as 'knowledge' [by] the man in the street" (1966: p. 3), an emphasis neglected by the classical sociology of knowledge. With reference to the phenomenology of everyday life of Alfred Schutz and the philosophical anthropology of Arnold Gehlen, Berger and Luckmann deliberately set aside the classical approaches of Marx, Mannheim, and to some extent also Scheler, with their epistemological and methodological concerns and their focus on absolutely valid knowledge, instead taking as their primary theme everything that counts as knowledge in society, including ideology, 'false consciousness,' propaganda, art and science (Gross, 2010: esp. 216–217; see also 2013). Their work may be regarded as an application of Durkheim's dictum that social facts must be considered as 'things,' that everything in society is a social product, a social construction. Social Facts are *sui generis*, the effect or the creation of human activities, but they are most often the unanticipated consequences of human agency or behavior.

Compounding these developments within specialty areas, including ethnomethodology, another subfield then on the rise (Maynard and Clayman, 1991), were broader trends in the social sciences during this period. Most far-reaching among these was a growing commitment to quantitative research, based increasingly on types of survey data that seemed remote from the traditional concerns of sociologists of knowledge. This trend, to be sure, coexisted with a heightening of interest in theory and in historical scholarship, but the Marxist renaissance that was then underway generally pulled this interest toward questions about the dynamics of modes of production and state apparatuses and toward debates about the role and concept of social class (and, subsequently, about gender and race). While new theories of ideology did emerge (see, in particular Althusser, 1969, 1971; Therborn, 1980), they did so, almost without exception, as appendages to work on class and state structures; as such, their effect was more to divert attention from, than to turn it to, examination of the sources and consequences of cognitive products and processes in their own right. In this context, little new work in the sociology of knowledge came forth, aside from reinterpretations of significant figures from earlier periods, especially Mannheim (see Simonds, 1978; Loader, 1985) and various editions of their original writings.

Just as exogenous developments during the two preceding decades threatened to imperil the sociology of knowledge, intellectual trends since the 1980s have resuscitated the field. Most generally these have included: burgeoning interest in the interdisciplinary field of cultural studies, also encouraged by the posthumous publication of Mannheim's early writings (1982a [1922–24]) in the sociology of culture (see Barboza, 2005, 2009; Corsten, 2010) and stimulated by a declining focus on Marxist structuralism and the growing influence of works on discourse and linguistic theory, poststructuralism, and postmodernism (for discussion, see McCarthy, 1996); the effort within Marxism itself to transform general claims about ideology into empirical studies of discursive formations and practices (Laclau and Mouffe, 1985; Thompson, 1990); the move within feminist scholarship to problematize knowledge and the standpoint and social position of knowledge producers (Harding, 1991; Smith, 1987; see also Kettler and Meja, 1993); the rediscovery of Mannheim's methodological reflections on the interpretation of word-views, which Mannheim called the 'documentary' method of interpretation (1952b[1921–22]: pp. 51–63; 1982[1924]: pp. 141–288), as one of the essential methods for interpretive, or reconstructive, qualitative sociological research (Bohnsack, 2007, 2008; Weller, 2005); the increased production of sociologically informed studies in the history of science and intellectual history (see Shapin, 1982; Toews, 1987); and the redirection of the sociology of science toward the examination of the contents of scientific knowledge and the social processes shaping them (see Collins, 1983). Reinforcing these broad trends has been an expansion of interest in European social theorists whose works give considerable attention to knowledge-production processes, particularly Michel Foucault and his archeological and genealogical studies of the reciprocal constitution of various knowledge systems and webs of power relations (see Prado, 1995), Pierre Bourdieu and his writings on the dynamics of intellectual and scientific fields (see Ringer, 1990; Camic, 2013), as well as Norbert Elias' figurational sociology and Niklas Luhmann's systems theory, both influenced by Mannheim's sociology of knowledge (Elias, 1971, 1981, 2009; Luhmann, 1980, 2008).

From this confluence of exogenous developments has come a renewed concern with the sociology of knowledge, a concern that is currently pulling the field in the direction of several different approaches. The first of these is the broad-constructionist approach, exemplified in programmatic statements by McCarthy (1996), Meja and Stehr (1988), Stehr and Meja (2005), and Swidler and Arditi (1994), and in studies by Griswold (1986), Lamont (1987), and Wuthnow (1989). Pointing the sociology of knowledge outward toward the contemporary sociology of culture rather than toward the study of knowledge specialists, this perspective treats "political and religious ideologies as well as science and everyday life, cultural and organizational discourses along with formal and informal types of knowledge" (Swidler and Arditi, 1994: p. 306); and while amenable to a middle-level or institutional analysis of the social sources and consequences of these various forms of knowledge, it often retains the underlying suppositions of the 1920–65 period, viz. assumptions about the division between external (sociocultural) and internal (thought-content) factors, about the transparency of internal meanings to the sociological investigator, and about the explanatory importance of macrolevel external factors. Moreover, while strongly committed to empirical research, this approach has also favored reopening some of the *meta*-theoretical issues that occupied earlier generations (see the contributions in Stehr and Meja, 2005).

In these ways, the broad-constructionist approach diverges from the recent narrow-constructionist alternative. Found in the work of Camic (1983, 1992; Camic and Xie, 1994), Collins (1998), Kusch (1995), and Shapin (1994), this second approach focuses the sociology of knowledge mainly on men and women who specialize in the production of ideas and on the particular social processes by which their ideas emerge and develop – a move that, in effect, transforms the field into a sociology of ideas. This perspective has tended to reject the core assumptions of the older sociology of knowledge, building instead on scholarship that argues that sociocultural processes are as much internal to the content of ideas as they are external (Bloor, 1976; Shapin, 1992), that the meanings of ideas are only understandable to an investigator after careful contextual reconstruction (Skinner, 1969), and that local, micro-level settings are often the main sites for the development of ideas (Geertz, 1983; Whitley, 1984). Like the broad-constructionist approach, this narrow-constructionist perspective presently provides a foundation for several lines of empirical research (see Camic and Gross, 2000).

Inspired by developments in the history of knowledge, sociologists of knowledge have also engaged in empirical analyses of the 'manufacture' of natural-scientific knowledge. The most important research tools have been ethnographies of laboratory life (Latour and Woolgar, 1979; Knorr-Cetina, 1981, 1999). These studies have led to a reassessment of the limitations of various types of knowledge, of the conditions of their origin, and of their structural qualities. Traditional theoretical assumptions about the specific rationality of scientific knowledge have been reassessed (Woolgar, 1988; Serres and Latour, 1995; Latour, 1999).

Lewis Coser observed that the ambitious project of the founders of the sociology of knowledge remains a continuing challenge, not an obsolete burden. In his survey of the history and prospects of the sociology of knowledge he writes:

> The sociology of knowledge was marked in its early history by a tendency to set up grandiose hypothetical schemes. These contributed a number of extremely suggestive leads. Recently its practitioners have tended to withdraw from such ambitious undertakings and to restrict themselves to somewhat more manageable investigations. Although this tendency has been an antidote to earlier types of premature generalizations, it also carries with it the risk of trivializations. Perhaps the sociology of knowledge of the future will return to the more daring concerns of its founders, thus building upon the accumulation of careful and detailed investigations by preceding generations of researchers.
>
> Coser, 1968: p. 432

Such a return of sociology knowledge practitioners to the more daring concerns of the founders cannot not exclusively result from intellectual and scientific efforts. Merton, for example, therefore emphasizes that interest in sociology of knowledge issues is itself socially conditioned. One important factor, as Merton argued, is that

> With increasing social conflict, differences in the values, attitudes, and modes of thought of groups develop to the point where the orientation which these groups previously had in common is overshadowed by incompatible differences. Not only do there develop distinct universes of discourse, but the existence of any one universe challenges the validity and legitimacy of the others.
>
> Merton, 1968b: p. 511

In this sense the reconstructions and interpretation of the sociology of knowledge by the generation of sociologists succeeding the generation of the founders, as well as the period of temporary waning of interest in sociology of knowledge issues discussed above, coincided with particular economic, political and social conditions as well as academic and disciplinary circumstances that, in their relative tranquility, stood in market contrast to the crisis conditions of the 1920s. The present renewal of interest in some of the major issues first articulated by the founders of the sociology of knowledge, in contrast, 'reflects' (just as in the earlier period in which the classical sociology of knowledge arose) the experience of crisis in present-day society (Beck, [1986]1992; Stehr, 2001).

Knowledge has always played a significant role in human life. Human action has to a greater or lesser extent always been steered by knowledge. Power, for example, has rarely been based exclusively on brute physical force, but almost always also involves a knowledge advantage. At present, however, knowledge is assuming greater significance than ever before. In spite of a simultaneous rise in interest in not-knowing and in knowledge gaps (Beck and Wehling, 2012; Gross, 2010), advanced societies may be regarded as 'knowledge societies' (Stehr, 1994). A thoroughgoing scientization of all spheres of human life and action, the transformation both of traditional structures of domination and of the economy, as well as the growing impact and influence of experts are all indications of the rapidly increasing role of knowledge in the organization of contemporary modern societies.

Abstract

First, a brief overview of Kohlberg's biography and some reminiscences by friends and colleagues highlighting some core characteristics of his personality are presented. His basic assumptions about the nature of human beings, of morality, and of psychology as a social science are briefly touched upon. Then, central features of this theory of moral development are explicated: the concept of a developmental logic, his description of the moral stages, the methods used, the mechanisms assumed to advance development, and implications for pedagogical intervention. Empirical support is discussed concerning the assumptions of the sequentiality, hierarchy and universality of moral development. Finally, some critical issues are taken up in the light of recent empirical findings: the judgment action gap and Kohlberg's descriptions of children's moral understanding. A new reading of moral development is suggested in which cognitive and motivational aspects are disentangled.

Kohlberg was born on 25 October 1927, in Yonkers, New York, the son of a Protestant mother – a well-known chemist – and a Jewish father – a successful self-made businessman with strong civic commitment and of conservative leaning. Kohlberg grew up in a liberal Jewish community. In 1945 he joined the US Merchant Marines; he then helped to smuggle East European Jewish refugees to Palestine, was seized by the British army, and was interned in Cyprus. He fled to Palestine and spent some time in a kibbutz – pondering issues of justice and violence. In 1947 he went to the University of Chicago, reading moral philosophy from Plato to Dewey, studying Locke, Mill, and Jefferson in search of a basic moral principle that might bridge disagreements – and discovered Kant's imperative: 'treat every human being as an end in himself.' He did graduate work in psychology, studying with Bettelheim, Rogers, Gewirtz, Morris, Newgarten, Havighurst, and Strauss – 'the first American scientist who attempted to integrate Piaget's structural theory with Mead's symbolic interactionism' (Kohlberg 1984, p.vii).

After two years of clinical work he started research for his doctoral dissertation on the development of moral judgment that he finished in 1958. From 1959 to 1961 he was assistant professor at Yale University; 1961–62 fellow at the Institute for Advanced Study in the Behavioral Sciences in Palo Alto; 1962–68 professor at the University of Chicago; 1968–87 professor at Harvard University. Having an incurable disease, on 17 January 1987 Kohlberg ended his life.

Kohlberg changed US psychology. His influence is due to intellectual brilliance, but also to an inspiring personality attracting scientists from all over the world. Kuhmerker et al. (1991) elicited personal letters from friends and colleagues describing what Kohlberg had meant for their lives. Some core characteristics emerge: Kohlberg was 'loveable' – and had 'a remarkable ability to insure this characteristic in those who worked with him ... all of whom had not only a peculiarly fanatical interest in the study of moral development but also a deep personal affection for Lawrence Kohlberg, the man.' (Grimley) Kohlberg was persistent; what struck Kegan was 'that an idea can be compelling enough and an individual devoted enough for the two to spend 25 years together in a relationship as fresh and combustible today as when it began.' Kohlberg was stern – demanding extraordinary efforts of himself and of others; he 'would call another scoring workshop whenever he felt his assistants were working less than 80 hours a week.' His commitment was contagious: 'At the Center of Moral Education there was a sense of being at the right place at the right time – that terribly new and important breakthroughs were just around the corner ... that questions of social justice were on everyone's mind and we thought we had the answers – or nearly had the answers.' He was 'a visionary' who kept 'the major questions in focus.' Had it not been for him 'many of us would not have become interested in psychology at all' (Rest, 1986).

For Kohlberg the unity of moral judgment and action was not just a theoretical stipulation – it was his very personality. A colleague recalls an occasion when he had initiated a resolution against the invasion to Cambodia. When the question arose who would accompany him in handing it over in Washington:

> ... the meeting became silent. Motionless. Eerily quiet. These giants of education who daily proclaimed the virtues of equality, of human rights, of democratic citizenship and had themselves just voted overwhelmingly in favor of the resolution now sat in perfect pose, looking at their shoes. Numbed and dazzled by this educational experience. I finally noticed one lone figure somewhat unkempt in attire standing next to me. Although I had met him a number of prior occasions, that was the time I really met Larry. (Sprinthall)

Kohlberg addressed important issues authentically and in an innovative way. This carried others along. Thus, Kohlberg's theory springs also from collective endeavors – initiated, inspired, and directed by Kohlberg, but advanced by his students, friends, and colleagues as well.

Kohlberg's Approach

Kohlberg's approach ran counter to the basic assumptions about the nature of human beings, of norms, and of science dominant at the time. Humans were seen as basically passive (shaped by reinforcement schedules in behaviorism, by parental authorities in psychoanalytic theories, or by the gradual unfolding of genetic endowments in maturationism) and primarily motivated by self-serving concerns (avoiding external or superego sanctions). In contrast, Kohlberg – following Piaget – viewed

people as active interpreters of their world and also motivated by intrinsic concerns (for mastery, truth, or other values).

Norms were seen as externally given contingent facts. Kohlberg, instead, viewed norms as propositions raising the validity claim of rightness, that is, in need of and capable of being justified. Psychology followed a natural science epistemology: copying or explaining reality is aimed for by standardizing measurement procedures or experimentally isolating and manipulating variables. In contrast, Piagetian analyses seek to trace universal developmental changes in subjects' interactive constructions of reality; hermeneutic interviews aim at objectivity by guaranteeing not the physical identity of the stimulus, but the identity of its meaning. Kohlberg was one of the pioneers in bringing this Piagetian cognitive frame to bear on academic psychology in the USA.

Also, his interest in moral reasoning was new. Up until then, only normconforming behavior (not moral action) or moral emotions (not moral judgment) had been studied – both from an observer's point of view. Kohlberg, instead, looked at morality from a firstperson perspective. And he did so with a specific – not uncontested – understanding of morality by focusing on judgment he excluded questions of moral character, of habitualized moral dispositions, of virtues. By defining morality on deontic terms he excluded questions of the good life that he left to ethics and/or to the personal domain. By identifying morality with a justice procedure he largely neglected content. By describing this procedure as 'moral musical chairs' he sketched a hypothetical role-taking procedure that remains entirely monological.

Moral Development

The Stage Model

Piaget had described young children's moral development as progress from a heteronomous stage (characterized by egocentrism; unilateral respect; a focus on consequences rather than on intention; an understanding of rules as objective, absolute and unalterable; a belief in immanent justice) to an autonomous morality produced by peer interaction and cognitive decentering. From his study of adolescent development Kohlberg derived a refined description of the stage model and of developmental mechanisms.

Development consists in changes in the reasoning structure justifying judgments of 'right' or 'wrong' and in the concerns motivating norm conformity. Its structural core is a widening of the sociomoral perspective. Universally, there are three levels with two 'hard' stages each. The model is based on the following assumptions:

- each stage is a structured whole that is qualitatively different from the others;
- the sequence of stages is invariant, irreversibly progressive without stage skipping;
- the stages form a hierarchy: higher stages are better differentiated and integrated structures that allow morally better solutions to dilemmas.

The stages are described as follows:

At the preconventional level (typical for most children under nine) situations are judged from a concrete individual perspective. Rules are seen to be external to the self. 'Right' is defined as obeying rules and authority, avoiding punishment, not doing physical harm (Stage 1) or as meeting one's own interests and letting others do the same (Stage 2); the reasons for doing right are to avoid punishment and to bow to the superior power of authorities (Stage 1) or to serve one's own needs or interests (Stage 2).

At the conventional level (typical of most adults) morality is judged from a 'member of society' perspective and is identified with socially shared internalized norms. 'Right' means living up to the expectations of one's group (Stage 3) or doing one's duty in society (Stage 4); the reasons for doing right are the need to be 'good' in one's own or others' eyes and caring for others (Stage 3) or the need to maintain a good conscience by meeting defined obligations (Stage 4).

At the postconventional level (reached by few adults only) moral values are defined from a 'prior to society' perspective in terms of self-chosen universal principles. 'Right' is upholding legal contracts (Stage 5) or is defined in terms of universal ethical principles such as equality and respect for the dignity of human beings as individuals (Stage 6). The reasons for doing right are obligations to the social contract (Stage 5) or a commitment to principles that have been rationally understood and accepted as valid (Stage 6).

Tests of Moral Development

In the Moral Judgment Interview (MJI, Colby and Kohlberg 1987) hypothetical moral dilemmas are given which allow of no 'right' answer (e.g., Should a man steal a drug to save his dying wife?). Subjects are first to decide what the protagonist ought to do (uphold the law or preserve life?) and then to justify and defend this decision against moral counterarguments advanced by the interviewer who aims at eliciting the subject's highest competence level. The responses are matched to structurally similar criterion judgments listed for each stage in the scoring manual.

In the Social Reflection Measure (SRM) Gibbs et al. (1992) developed a brief interview and coding manual that can be used for younger children. Objective tests have also been developed in which subjects rank their preference for a set of standardized responses that express stage-specific considerations (Rest's Defining Issue Test, DIT; Lind's Moral Judgement Test, MUT). Preference measures produce scores that are consistently (about one stage) higher than spontaneously produced answers, yet do correlate in medium range with scores in MJI.

Mechanisms of Development

In contrast to social learning and psychoanalytic theories which assume identification or modeling as the primary developmental mechanisms, cognitive theories see development as a result of internal restructuring in response to cognitive conflict. There is experimental evidence in support of this mechanism (cf Walker, 1986). The need to reconcile conflicting views may be the reason why taking leadership roles advances moral development.

This understanding of developmental mechanisms has inspired pedagogic interventions. Classroom discussions of moral dilemma tend to produce (albeit slight) moral growth.

The institutionalization of just communities, that is, structures allowing for democratic self-government, have been shown to improve the moral atmosphere of schools or prisons considerably and generate feelings of reciprocal responsibility (Higgins et al. in Kurtines and Gewirtz 1984).

Empirical Support and Criticisms of the Stage Model

Sequence

Age and stage have been shown to correlate in cross-sectional studies. Regression or stage skipping have rarely been found in longitudinal studies and not been induced in experimental studies designed to produce moral development (Snarey, 1985; Walker, 1986). Thus, the claim of a developmental sequence and of an invariant order stands.

Hierarchy

There is conceptual and empirical support for the claim of hierarchy. Conceptually, the stage sequence comprises an increasing universalization of perspectives (isolated individual; dyad; group; a given society; a democratically organized society; humanity at large) and an expansion of relevant concerns (negative and positive consequences to the actor; intentions; role obligations; societal institutions and legality; universal rights). Postconventional thinking makes it possible to integrate and balance these different concerns in view of universal principles of equality and respect for the individual. Empirically, subjects prefer higher and reject lower stage reasoning.

Universality

Kohlberg has been accused of ethnocentrism and gender bias in claiming universal validity for a stage model that was initially developed from interviews with males in the USA only. Two issues are at stake: first, is there a universal core to morality, and second, is Kohlberg's stage sequence universal? The first issue is dealt with theoretically in moral philosophy and practically in endeavors to win worldwide acceptance for human rights. The second issue sparked extensive empirical research (*see* Gender Differences in Personality and Social Behavior; Ethnocentrism).

The universal presence of Stages 1–4 is reported in a review of 45 studies from 27 widely diverse cultures involving over 5000 subjects. Postconventional thinking was found in urban samples only, not in traditional tribal or village societies either in Western or non-Western cultures (Snarey, 1985). Principled thinking thus seems a 'metalevel' feature necessary for adjudicating conflicts between subculture-specific norms and not required in normatively integrated and isolated cultures.

Gilligan (1982) has claimed the existence of two moralities: a rigid justice orientation more typical for males (corresponding to Stage 4) and a flexible morality of care and responsibility more typical for females (corresponding to Stage 3). Empirically, reviews of research involving 19 000 subjects have shown that either there are no stage differences between the sexes (Lind et al., 1987) or else they tend not to disadvantage women, or to disappear when education and employment are controlled for (Walker, 1984). Conceptually, Gilligan starts from a more encompassing understanding of morality than Kohlberg by including questions about the good life. Also, there are some theoretical confusions: 'care' often is experienced as a 'duty' by women, and flexibility – if not a mere reflection of powerlessness – seems a correlate of a modern secularized moral understanding ('ethics of responsibility,' Max Weber) rather than of sex membership.

Another View of Moral Development?

One core issue concerns the relationship between judgment and action. This problem has been dealt with in several ways. First, the claim was raised and empirically supported that consistency will increase with moral development (Kohlberg and Candee, 1984; Blasi, 1980). This makes sense given that subjects referring to self-serving concerns will be assigned to lower stages. Later, responsibility judgments (expressing the personal relevance of moral judgments, Higgins et al., 1984; Blasi, 1984), and the distinction between types A (considering pragmatic concerns) and B (exclusively focusing on moral values) have been introduced (Kohlberg, 1984; Colby and Kohlberg, 1987). These additions are remedies to deal with the fact that individuals differ in intensity of moral commitment – as is especially clearly evidenced by Colby's and Damon's (1994) 'moral exemplars.'

A more far reaching theoretical revision, however, may be called for in view of recent studies on children's moral understanding. Turiel (1983) and Nucci and Turiel (1993) have shown that young children distinguish between moral rules (enjoying universal, unalterable, intrinsic validity) and conventional or religious rules (that depend on authorities or God and are valid only for in-group members). Nevertheless, most young children expect a wrongdoer to feel good and only gradually begin to ascribe negative emotions (Nunner-Winkler and Sodian, 1988). Until about 6 or 7 years (i.e., before self-reflexive role-taking is developed) these predict moral behavior. By about 10 years almost all children (even those low in moral motivation) say they expect a wrongdoer to feel bad. In justifying these negative emotions most children tend to refer neither to impending sanctions nor to empathic identification with the victim but to the fact that a wrong had been committed. These departures from Kohlberg's description of preconventional thinking result from differences in problems addressed and measurement procedures used: Turiel and Nucci and Lee questioned children's understanding of norm validity. Nunner-Winkler focused on the intensity and type of moral motivation. Kohlberg asked for action recommendations in moral dilemmas. Until they begin to care about morality children will guide these along prudential rather than moral considerations.

A new reading of moral development suggests itself. Universally, children acquire an early understanding of the categorical ought: they know that moral norms are intrinsically valid and motives should not be self-serving. Thus, from early on, all have a good cognitive grasp of the constitutive feature of the moral domain – its deontic character. Moral competence, however, requires more. Sociocognitive development (which constitutes the structural core of Kohlberg's stage descriptions) and the acquisition of knowledge are needed for passing judgments in more complex situations. Moral motivation is needed to translate knowledge into action. These requisites are acquired in later and differential learning processes.

Kohlberg's Legacy

In discussing Kohlberg's contribution, Rest (in Kuhmerker et al., 1991) notes that the stage concept may dwindle away and additional variables (e.g., content, motivation, or character) may prove of import. What will remain is Kohlberg's part in the paradigm shift from behaviorism to cognitive psychology. More specifically, what will remain is his emphasis on the cognitive side of morality; his striving for reconstructing it from a participant perspective and linking it with philosophical quests for justifiability; his insistence that intrinsic motivation exists (still an urgent claim given rational choice reductionism); his emphasis that there is more to morality than 'being friendly with your friends' (Rest, 1986). In theory and practice Kohlberg was committed to an understanding of morality that demands building just institutions and treating all human beings with equal respect.

Abstract

Wolfgang Köhler, a German–US psychologist, was one of the founders of the Gestalt school of psychology in the beginning of the twentieth century. The scope of his scientific contributions was extremely broad, ranging from sensory psychophysics to theoretical physics, and the logic of discovery, and from perceptual psychology to animal cognition, and human values. Köhler's experiments with chimpanzees made him internationally famous; together with Max Wertheimer (1880–1943) and Kurt Koffka (1886–1941) he became an influential scholar first in Germany and then, after his emigration (1935), also in the USA. Early in his career, Köhler demonstrated the ape's so-called 'transposition' of perceived stimulus relationships; however, his speculative neurophysiology of perception was refuted on both experimental and theoretical grounds. Today his work in general is seen as a major breakthrough in animal problem solving as well as in human perception and cognition. After World War II, Köhler received numerous honors; and he was president of the American Psychological Association for the 1958–59 term.

Wolfgang Felix U. Köhler, a leading German–US psychologist in the twentieth century, was born to Franz E. Köhler, a German gymnasium (high-school) teacher and his wife Wilhelmine on 21 January 1887 in Reval (today, Tallinn), Estonia, at that time a part of the Russian Empire. Köhler's experiments with apes made him internationally renowned early during his long scientific career. As a cofounder of a school called Gestalt psychology, together with Max Wertheimer and Kurt Koffka, he became an influential scholar many years before he left Europe to join the faculty of Swarthmore College, Pennsylvania in the USA (see Table 1).

Major Events in Wolfgang Köhler's Life and Work

After his graduation from high school in 1905, Köhler undertook university studies in philosophy, history, and natural science in Tübingen, Bonn, and then Berlin, where he concentrated on psychology under Carl Stumpf's supervision. Besides his studies in experimental psychology, especially in psychoacoustics with Stumpf, he continued to pursue his interests in natural science and physics under Max Planck and Walther Nernst. In his doctoral dissertation, which he finished in 1909, he combined physical acoustics with psychoacoustics. This research, published in the same year in the *Zeitschrift für Psychologie*, demonstrated his great talent as a scientist. His findings forced his teacher Carl Stumpf to revise and do further research on his own psychoacoustical theories.

As an assistant at Frankfurt's institute of psychology (1909–13) under its director Friedrich Schumann, Köhler worked with Max Wertheimer and Kurt Koffka, who also had been trained in natural science and experimental psychology. This cooperation led to a life-long exchange among these three men, each of them involved in the advancement of psychological theory and research. Köhler worked on the then widely accepted '*constancy hypothesis*,' continued his psychoacoustical investigations in Frankfurt, and in his paper on '*unnoticed sensations and errors of judgment*' (1913) merged his individual line of research with that of Max Wertheimer's pioneering Gestalt work (King and Mich. Wertheimer, 2005).

From 1913 to 1920, Köhler conducted research on the mentality of apes, chickens, and children at the anthropoid

Table 1 Chronology: major events and dates in Wolfgang Köhler's life and work

1887	Born on 21 January 1887 in Reval (Tallinn), Estonia
1905–09	University studies in Tübingen, Bonn, and Berlin
1909	Doctoral dissertation thesis with Carl Stumpf at Berlin's Institute of Psychology
1909–13	Assistant at Frankfurt's Institute of Psychology; collaboration with Max Wertheimer (1880–1943) and Kurt Koffka (1886–1941)
1911	*Privatdozent* (lecturer) at Frankfurt
1913–20	Director of the Anthropoid Station on Tenerife; first epoch-making publications on 'transposition' and 'insight' in the chimpanzee
1920	Book: Treatise on Gestalt phenomena in natural sciences (*Die physischen Gestalten in Ruhe und im stationären Zustand: Eine naturphilosophische Untersuchung*)
1921	Professor at Göttingen. Founding of the journal *Psychologische Forschung* (*Psychological Research*), together with Max Wertheimer, Kurt Koffka, and others; major journal of Gestalt psychology (until 1938)
1922–35	Full professor of psychology and director of Berlin's Institute of Psychology
1925	Book: *The Mentality of Apes* (trans. from the 1921 German book)
1929	Book: *Gestalt Psychology* (later ed. 1947)
1935	Final clash with the Nazi authorities in Berlin and emigration to the USA; psychology professor at Swarthmore College until 1958
1938	Book: *The Place of Value in a World of Facts*
1944	Influential research publication on 'figural after-effects' (together with Hans Wallach)
1954–56	Perceptual research at the *Institute for the Advanced Studies* in Princeton, NJ
1958–59	President of the *American Psychological Association* (USA)
1959–67	Perceptual and psychophysiological research at Dartmouth College, New Hampshire (USA)
1967	Deceased on 11 June 1967 in Enfield, New Hampshire (USA)

research station of the Prussian Academy of Sciences on Tenerife, Canary Islands. He began his investigations with perceptual and problem-solving tasks, demonstrating the ape's and the chicken's size constancy and their transposition of perceived stimulus relationships. He also demonstrated the chimpanzee's fabrication and use of simple 'tools.' Most famous became the success of one of his apes named Sultan in fitting together two sticks to make them long enough to reach the goal object, a banana. Köhler (1917, 1921) also did extensive work on the chimpanzees' ability to solve a problem by stacking boxes on top of each other, thus demonstrating, once again, 'insightful' animal behavior. Köhler (1920; see **Table 1**) expanded the Gestalt-theoretical perspective when he wrote his treatise on '*Die physischen Gestalten in Ruhe und im stationären Zustand*' ('The physical configurations at rest and in stationary states'), a book in which he aimed to integrate basic principles in psychology and physics in a new psychoneural solution to the mind-body problem (see Section Köhler's Accomplishments and His Impact on Psychology). He became a professor at Göttingen's psychology institute for a short time (1921) before he followed Carl Stumpf in the chair at Berlin.

In 1922 Köhler became full professor of philosophy and director of the Psychological Institute at the University of Berlin, where he worked together with other eminent scientists like Max Wertheimer and Kurt Lewin. Here the international fame of the Berlin School of Gestalt psychology grew until its peak in the early 1930s. It was during this time that the Gestalt principles of the organization of perception were published and extended to new research issues (Wertheimer, 1923) like memory, cognition, motivation, and aesthetics.

During these years Köhler also lectured abroad several times, in the USA at Clark University (1925–26) and at Harvard University (1934–35), in South America in Uruguay (1930), as well as in Brazil and Argentina (1932). When Köhler encountered the harassment of university scholars by the Nazi government in 1933, he fought racial discrimination and struggled against the political authorities of those days; he may have been the only psychology professor in Germany who protested in public against the totalitarian system (Henle, 1978). When in 1935 his assistants were fired, he left Germany and followed his colleagues into exile in the USA.

In 1935 Köhler became a psychology professor at a small but prestigious undergraduate college, Swarthmore, near Philadelphia. There he continued his research, but on a smaller scale as his efforts were hampered by the absence of advanced facilities and the lack of a doctoral program at this institution (King and Mich. Wertheimer, 2005; cf also Ash, 1995; Sarris, 1995).

Nevertheless, Köhler, together with his American colleagues and students, published important new findings on figural after-effects and on related perceptual phenomena; he also studied the cortical activity associated with pattern vision (see Section Köhler's Accomplishments and His Impact on Psychology below), and wrote three further books on Gestalt psychology, all in English (Köhler, 1958).

After World War II, Köhler received worldwide recognition for his life work, including several honorary doctorates from American and European universities. He was a recipient of the APA's (American Psychological Association) Distinguished Scientific Contribution Award and was elected a Member of the National Academy of Sciences. He was also named an 'honorary member' (*Ehrenbürger*) of the Free University of Berlin, where he lectured several times, first as a visiting professor. He was elected president of the APA for the 1958–59 term, an unusual honor for an emigré scientist in the USA (Sarris, 2002).

Köhler's Accomplishments and His Impact on Psychology

Gestalt theory had begun after the turn of the twentieth century as a scientific revolt, first against Wilhelm Wundt's ruling elementaristic ('atomistic') approach, and later opposed to John Broadus Watson's – then dominant – behaviorism. It took several decades before Gestalt theory became a fully acknowledged perspective in psychology.

Köhler's ideas about thinking were opposed strongly to those of the other schools of psychology. Some of his research was specifically directed against E.L. Thorndike's influential behavioristic interpretation of learning and problem solving in animals. According to the latter view, a correct behavioral response occurs in the course of blind trial-and-error activity; on repeated trials the correct response is reinforced and thus strengthened simply by association in an 'automatic' way (Thorndike's 'law of effect'). Köhler, in sharp contrast to that approach, argued that Thorndike's puzzle-box task did not allow any perceptual-cognitive insight into the whole procedural arrangement and thus represents no possibility of real problem solving; 'insight' requires a situation which is completely 'natural' and 'visible' to the animal (Köhler, 1921).

According to Köhler (1951), problem solving is based on the organization of meaningful relations. It begins with a situation and a goal that cannot be directly reached (the so-called 'detour' problem). The process of problem solving requires a reexamination of the situationally given materials which must be 'reorganized,' quite analogously to the reversal of perceptual patterns. Köhler was criticized by his opponents for not considering the influence of past experience on problem solving. He did not deny the role of past experience in principle, but considered it of minor significance in insightful learning. This issue has still not been fully resolved today.

Basic to Köhler's perceptual research was the study of stimulus relationships, starting with his comparative work on transposition in apes, chickens, and children (Köhler, 1917); for example, a chicken is presented with two gray samples, a darker one, *A*, and a lighter one, *B* (the positive stimulus): after successful discrimination training the chicken is tested with a new pair of samples, *B* and *C* (*C* being lighter than *B*). The majority of Köhler's hens chose *C* over *B*, thus showing relative choice behavior ('transposition'). Köhler obtained similar experimental results with his chimpanzees as subjects, using size as well as brightness as stimulus dimensions, thereby demonstrating the priority of 'structural' properties in perception and learning. From the perspective of Gestalt theory, the effective stimulus for a given perception or

perceptual choice is always relational in character; what is perceived and reacted to is fundamentally a given 'pattern,' which is conceived of as the interaction (relation) between a particular stimulus and its surround. This idea, although challenged by the behaviorist school, has been proved to be accurate, by and large; it fits with the Gestaltists' emphases on the importance of the *frame of reference* in perception (cf Sarris, 1994, 2006).

Köhler's interest in the physical processes in the brain, which dates back to his years on Tenerife (or even before), generated an influential book on a special psychoneural theory of perception. This monograph (1920) dealt with the neurophysiological processing during a given experience, in an attempt to relate the laws of physics to the brain's physiochemical characteristics. It was to this end that he later directed his research on figural after-effects and so-called satiation (Köhler and Wallach, 1944). His explanation for these much – investigated phenomena was based on the notion that direct electric currents are generated in the cortex, resulting in different active 'fields' for various perceptual phenomena (Köhler and Held, 1949). However, this theory was not accepted widely by the scientific community; on the contrary, it was later refuted on both experimental and theoretical grounds in criticisms of Köhler's speculative psychophysical isomorphism.

Köhler expanded the Gestalt principle of perceptual and cognitive organization to the province of memory and learning by assuming that recognition and recall are functionally another case of grouping. When a form or pattern is perceived it tends to be subsequently recognized and recalled in a well-structured, organized way; memory traces in the brain are conceived of as neurophysiological correlates of recognition and recall.

Köhler (1947) developed several criticisms of classic associationist psychology. For instance, he attacked the 'law' of association by contiguity as being merely a mechanistic principle:

> Two processes A and B happen to occur together and, whatever the nature of A and B may be, a bond is formed between them! I do not know a single law in physics or chemistry which could in this respect be compared with the law of contiguity.
>
> Köhler (1947)

Köhler argued that meaningful pairs of words are always associated more readily than are pairs of nonsense elements as the former can more easily ('naturally') be organized into a unified pattern ('Gestalt'). According to this account, recognition and recall depend on an interaction between the assumed memory traces that are relationally determined (Köhler, 1951; see the reference details in Sarris, 2006).

Köhler's and his followers' work gradually influenced the direction and content of modern psychology. Gestalt psychology turned out to offer an important alternative to behaviorism and its related perspectives, especially in the fields of perception and cognition, since the 1960s in the twentieth century.

Köhler was a research-oriented scientist aiming at an integrative and multidisciplinary development of psychology as a science. His work is now seen as a theoretical and experimental breakthrough in animal problem solving and in human perception and cognition. Nowadays modern psychophysical and neurobiological theories are being used to reexamine the classic Gestalt issues.

Some of the central tasks of the brain – such as figure-ground coding, perceptual organization, object identification, and the formation of object memory – concern the integration of separately coded stimulus features into coherent and meaningful object representations. These fundamental problems of explaining the basis of perception and cognition, namely the understanding of the computational or informational significance of neurobiological activity, have not been solved so far. Nowadays these issues are approached by the concerted efforts of different disciplines (notably, psychophysics, neurobiology, and neurocomputing; e.g., Spillmann, 2012).

Köhler also envisioned the science of psychology as an expanding area to be developed according to an ethical understanding (Köhler, 1969). His analysis of values and human ethics led Köhler to reject the commonly held assumption that values are merely subjective; on the contrary, his position offers an alternative to the relativism that seems to dominate discussions of values in science and life.

Final Notes

Köhler died on 11 June 1967, at the age of 80 at his home in Enfield, NH, USA. There has been a Wolfgang Köhler Society on Tenerife, Spain, since 1992; and the Wolfgang Köhler Memorial Lectures are organized biannually by the *Deutsche Gesellschaft für Psychologie*, Today there is also a "Wolfgang Köhler Primate Research Center" at the Max Planck Institute for Evolutionary Anthropology in Leipzig, Germany. Germany's national psychology association. The Wolfgang Köhler Archives are housed in the Archives of the Philosophical Society of America in Philadelphia. The complete bibliography of Köhler is published in Henle (1971).

Abstract

This article – after giving an overview on Emil Kraepelin's life – discusses Kraepelin's concept of mental illness in general and psychiatric research in particular. Although he was hardly interested in philosophical presuppositions of psychiatric work, his publications prove the influence of major theoretical concepts like realism, naturalism and parallelism. The basic idea of 'natural disease entities' in psychiatry and the development of Kraepelin's clinical nosology over a period of nearly 50 years is then described before focusing on the significant influence Kraepelin still has on present-day psychiatry, especially with regard to psychiatric diagnoses and research. However, in recent years the 'neo-Kraepelinian' perspective has also been criticized substantially especially with regard to the nosological dichotomy of schizophrenic and affective psychoses. A thorough knowledge and balanced interpretation of Kraepelin's work is indispensable for a clear understanding of this debate and for its further development.

Biographical Note

Emil Kraepelin was born on 15 February 1856 in Neustrelitz (Mecklenburg, West Pomerania, Germany). He studied medicine in Leipzig and Würzburg from 1874 until 1878. During his medical studies in Würzburg, Kraepelin worked as a guest student at the psychiatric hospital under the directorship of Franz Rinecker. He began his professional life in 1878 working with Bernhard von Gudden at the District Mental Hospital in Munich, where he stayed until 1882. Kraepelin then moved to Leipzig, where he worked with Paul Flechsig and Wilhelm Erb. He was promoted to university lecturer there in 1883.

His lifelong personal and scientific relationship with Wilhelm Wundt began in Leipzig. Encouraged by Wundt, Kraepelin, at the age of 27, wrote his *Compendium of Psychiatry* in 1883, the precursor of his influential textbook *Psychiatry*, which was published in nine editions between 1883 and 1927. Kraepelin stayed in contact with Wundt by correspondence and paid him several visits before Wundt's death in 1920; in many of his publications he emphasized and acknowledged the importance of this relationship.

In 1884 Kraepelin married Ina Schwabe. After a short period of employment in Leubus (in Silesia) and Dresden, Kraepelin was appointed professor of psychiatry at the University of Dorpat in 1886. In 1891 he took over the chair of psychiatry at the University of Heidelberg. From 1903 until 1922 Kraepelin was ordinary professor of psychiatry in Munich where, in 1904, he opened the new building of the psychiatric hospital of the Ludwig Maximilian University, the main part of which is still in use. Despite the difficult conditions caused by World War I, Kraepelin founded the *Deutsche Forschungsanstalt für Psychiatrie* (the German Research Institute for Psychiatry) in Munich in 1917 to encourage and improve psychiatric research (Weber, 1991). During his time in Munich, Kraepelin's colleagues at the university hospital and the *Forschungsanstalt* included Alois Alzheimer, Franz Nissl, Korbinian Brodmann, Walter Spielmeyer, August Paul von Wassermann, and Felix Plaut – to mention but a few. In 1924 the *Deutsche Forschungsanstalt* was integrated into the Kaiser Wilhelm Society and became in 1945 the Max Planck Institute for Psychiatry as part of the Max Planck Society. Emil Kraepelin died in Munich on 7 October 1926. Kraepelin's memoirs were published in German (1983) and in English (1987).

Kraepelin's Concept of Psychiatry as a Science

Three important authors who strongly influenced Kraepelin's understanding of psychiatry have to be mentioned: Griesinger, Kahlbaum, and Wundt.

Wilhelm Griesinger had marked the turning point in nineteenth-century psychiatry by calling for thorough clinical and pathophysiological research based on the premise that 'mental illness is an illness of the brain.' But Griesinger's theory was by no means as simple as this one statement, which is so often quoted. He held differentiated views on the problem of somato- and psychogenesis, although favoring the first in the case of what was later to be called 'endogenous psychoses.'

Karl Ludwig Kahlbaum continued the traditions of French psychopathology as represented by Jean-Pierre Falret and Antoine Laurent Jessé Bayle. He developed a clinically orientated research method in the second half of the nineteenth century in Germany, strongly focusing on the course of illness. This, like Griesinger's theory, was believed to be a victory over the speculative concepts of the so-called 'romantic medicine' and even more so an argument for a critical distance to the position of the harsh and unreflected 'somaticists,' who were no less dogmatic than some of the 'psychicists.' Kahlbaum had clearly recognized the conceptual and methodological differences between neuroanatomical and psychopathological approaches. With 'progressive paralysis of the insane' as an example he explained the route from the 'syndrome-course unit' (*Syndrom-Verlaufs-Einheit*) to the – postulated – etiologically based 'disease unit' (*Krankheitseinheit*).

The influence of Wilhelm Wundt, one of the founders of experimental psychology, on Kraepelin can hardly be overestimated. Wundt's aim, on the one hand, was to establish psychology as a kind of natural science using an experimental approach to collect data. In this line of thought, he criticized the highly speculative approach of 'philosophy of nature' in the

sense of Schelling and Schleiermacher. On the other hand, he did not agree with materialism or association psychology in the sense of Herbart. Especially in his earlier writings, Wundt clearly favored a parallelistic point of view in the mind–body problem. The young Kraepelin was highly impressed by these Wundtian ideas since they allowed experimental research to be successfully applied in psychology without ignoring the epistemological differences between the mental and the physical. Along the years, Kraepelin modified Wundt's concepts by extracting what he regarded useful for empirical research in clinical psychiatry. That is why Wundt's psychology, viewed through the 'filter' of Kraepelin's texts, seems much more unified and straightforward than it really was. In brief: Kraepelin simplified and, so to speak, 'smoothed out' Wundt's concept, but he did not falsify it.

Kraepelin was not profoundly interested in the philosophical basis and implications of psychiatry. His view of what (natural) science was, and what impact it had or should have on social and political developments, was, as Engstrom (1991, 1995) has shown convincingly, typical for the way natural scientists saw themselves at the turn of the last century. However, despite his skeptical attitude toward continuous philosophical reflections in psychiatry, the following major theoretical frameworks can be identified as underlying – seldom explicitly, most often very implicitly – Kraepelin's concept: realism, parallelism, experimental approach, naturalism.

Realism

Kraepelin, like most of his contemporaries in academic psychiatry, believed in an independently existing 'real world' that includes other people and their healthy or disturbed mental processes. Kraepelin repeatedly pointed out that the psychiatric researcher has to describe objectively what 'really' exists and what 'nature presents to him' – the formulations differ, but the essence is always a strictly realistic philosophy. The consequences for psychiatric nosology are evident: such realism will lead to the concept of 'natural disease entities' which exist independently of the researcher. The scientist describes what he finds, or – in stronger terms – describes 'given things.' His own activity in constructing scientific hypotheses or diagnostic entities is underestimated or may even be overlooked.

Parallelism

Kraepelin advocated psychophysical parallelism. Like Wilhelm Griesinger, whom he admired for his critical attitude toward speculative psychiatric theories, he disapproved of reductionistic materialism which *identifies* mental events with neurobiological processes. Kraepelin spoke about two kinds of phenomena, somatic and psychological, which are decidedly different, but closely connected. He defended the existence of mental phenomena against all kinds of what he, like Karl Jaspers, called 'brain mythologies.' Contrary to Wundt, however, Kraepelin, although calling himself a parallelist, did not enter the widely ramified philosophical debate on this issue. In particular, he did not critically differentiate between parallelism and interactionism, nor did he realize that any strictly defined parallelism makes it more than doubtful if mental phenomena still may be regarded as an independent sphere and not just as having a one-to-one relationship with the somatic level. The latter option, of course, comes close to (causal) determinism.

As a consequence of his ambivalent, if not blurry position in the mind–body debate, there indeed is an implicit tendency toward monism in Kraepelin's writings, particularly when it comes to his ideas about psychology as a natural science. But it should be emphasized that this 'monistic tendency' was not a metaphysical one, but a weak version of what may be called 'methodological monism,' insofar as Kraepelin decidedly favored the quantitative methods brought forward by the natural sciences (Verwey, 1985).

Experimental Approach

Kraepelin argued that the psychological and psychophysiological experiment should become a major scientific tool to reach a more profound understanding of disturbed, but also of healthy mental processes. Both Wundt and Kraepelin realized the difference between a physical and a psychological experiment, but in their view the experimental design as such did not differ significantly in both areas. Kraepelin seems to have considered the experimental approach a kind of guarantee for the scientific status of psychiatric research. From this it may be inferred that he rated the experimental approach higher than the mere description of clinical phenomena, although, of course, he accepted and even stressed the latter method as indispensable tool, especially if combined with follow-up examinations. In conclusion, Kraepelin developed and maintained a skeptical attitude toward subjective – especially biographically determined – aspects of mental disorders, which could not be studied experimentally.

Naturalism

In his early writings – mainly in those on forensic topics – Kraepelin clearly expressed his opinion that a priori ideas (in Kant's sense), freedom of the will, and unquestionable moral values do not exist. For him, man is nothing but a part of nature, and, consequently, anything man can do is a product of this natural existence. This position brought Kraepelin very close to what is nowadays called 'evolutionary naturalism' (Hoff, 1998). Later in his life, he became somewhat more cautious concerning these matters, but there is no reason to believe that he substantially changed his mind. This naturalistic, 'antimetaphysical' point of view, of course, made Kraepelin feel sympathetic with Darwinist and biologistic theories, although he always rejected oversimplifications such as those in the monistic theories of Ernst Haeckel, Jakob Moleschott, and Ludwig Büchner.

Kraepelin and Degeneration Theory

There are strong links between the basically naturalistic attitude of most academic psychiatrists in the end of the nineteenth century and the increasing influence of degeneration theory, although both aspects should, of course, not be mixed up. This

issue is discussed here in some detail, because there has been substantial criticism toward Kraepelin's broad, albeit not fully uncritical acceptance of degeneration theory. His position was even said to have carried "overtones of protofascism" (Shepherd, 1995a,b).

Degeneration theory is far from being only a psychiatric or even medical issue. It had gained wide influence not only in scientific, but also in philosophical and political circles in the last decades of the nineteenth century. As for psychiatry, it had important roots in French psychopathology, especially in the writings of Bénédict Augustin Morel and Valentin Magnan. The central idea of this concept was that in 'degenerative' illness there is a steady decline in mental functioning and social adaptation from one generation to the other. For example, there might be an intergenerational development from nervous characters to major depressive disorder, then to overt psychotic illness and, finally, to severe and chronic cognitive impairment, i.e., dementia. It should be noted, however, that this theory has always been a vague and speculative concept, which was brought forward decades before the rediscovery of Mendelian genetics and their application to medicine in general and to psychiatry in particular (Chamberlin and Gilman, 1985; Dowbiggin, 1985; Hermle, 1986; Liegeois, 1991; Pick, 1989).

Kraepelin and with him most of the contemporary authors of psychiatric textbooks used arguments derived from degeneration theory broadly. He made a special reference to them with regard to manic-depressive illness, paranoia and personality disorders. However, like in his Swiss colleague Eugen Bleuler in Zurich, Kraepelin's attitude toward degeneration theory was not straightforward positive, but included critical arguments. For example, although commenting approvingly on the basic ideas of Cesare Lombroso's 'criminal anthropology,' Kraepelin did not accept the idea of overt 'stigmata degenerationis,' by which individual persons could be identified as being 'degenerated' simply by their physical appearance (Zubin et al., 1985).

To sum up this aspect, there is no doubt that Kraepelin, on the one hand, in many respects accepted degeneration theory and implemented it into the debate on etiology and pathogenesis of mental disorders. On the other hand, it is not appropriate to draw a *simple and direct* line from earlier versions of degeneration theory to the horrible crimes against the mentally ill that were committed during the period of National Socialism. A differentiated view is needed here, which will only be reached by thorough and unbiased research (Hoff, 2008).

Kraepelin's Psychiatric Nosology

Basic Aspects

On the clinical level, Kraepelin changed the details of his diagnostic system over and over again. On the basic level, however, his nosology showed remarkable stability over time: between the second and the ninth editions of his textbook (i.e., from 1887 to 1927) Kraepelin did *not* change the central postulate: He stated that the essential features of all psychotic disorders will eventually be classified in a 'natural' system, no matter which scientific method is applied, pathological anatomy, etiology or clinical symptomatology including long-term course of illness. All these approaches will necessarily converge in the same 'natural disease entities,' simply because they are 'natural kinds' that are detected, not constructed by research (see **Figure 1**).

Figure 1 Kraepelin's disease concept.

Kraepelin limited this strong hypothesis to a certain extent in three theoretical papers, written between 1918 and 1920: 'Ends and means of psychiatric research' ('*Ziele und Wege der psychiatrischen Forschung*'; 1918), 'Research in the manifestations of mental illness' ('*Die Erforschung psychischer Krankheitsforme*'; 1919) and 'Clinical manifestations of mental illness' ('*Die Erscheinungsformen des Irreseins*'; 1920). In these papers Kraepelin took into account contemporary arguments such as Karl Birnbaum's differentiation between pathogenetic and pathoplastic factors in mental illness or Robert Gaupp's hypothesis of the possibility of psychogenic delusion; Kraepelin now acknowledged the value of defining certain syndromes as a middle course between nosologically unspecific symptoms and specific diseases. But – and this is essential – at no time did he abandon his postulate of underlying distinct and natural disease entities (Hoff, 1994, 1995).

Clinical Aspects

Kraepelin's clinical nosology is best separated into three periods. The early period, 1880–91, is characterized by the search for a reliable and valid psychiatric system between clear-cut naturalistic beliefs and the methodological framework of experimental psychology in the sense of Wundt. As for nosology, Kraepelin slowly moved away from earlier nineteenth-century concepts which he criticized as unreliable and ill-defined from a clinical and, especially, prognostic point of view. In these years the term '*dementia praecox*' was not yet used. A group of clinically heterogeneous paranoid and hallucinatory psychoses tending to chronicity was labeled '*Wahnsinn*' (insanity). It probably resembled the cases now known as schizophrenic psychoses developing residual states. In addition, Kraepelin introduced '*Verrücktheit*' (madness) as a chronic psychosis with a better prognosis, that explicitly did not lead to residual states. The affective

psychoses were split into three groups: melancholia, mania, and periodical or 'circular' psychosis.

In the middle period, 1891–1915, Kraepelin's thinking reached its most systematic and influential level regarding its clinical as well as scientific implications: Kraepelin significantly broadened his clinical experience and self-consciously created a complete nosological system. He finalized his concept of 'natural disease entities' as discussed above. The main clinical result of this period – first clearly proposed in the sixth edition of 1899 – was the well-known dichotomy of endogenous psychoses: that is, the separation of *dementia praecox* with – as he saw it – a poor prognosis, from manic-depressive illness (bipolar disorder) with a good, or at least better, prognosis. With respect to *dementia praecox*, he supposed an organic defect as the basis of the illness, a kind of 'autointoxication,' leading to the destruction of cortical neurons. The patient's personality may promote the development of the psychotic illness, but it is not a central pathogenetic factor; contrary to most other nosological areas, 'degeneration' was believed to be of much less importance in *dementia praecox*. 'Paraphrenia' was conceptualized as a psychosis with acute and heterogeneous clinical symptomatology, including the development of lasting deficits. Its separation from typical cases of *dementia praecox* was justified by the postulated absence of massive disturbances of volition and by a much lesser degree of affective flattening.

In manic-depressive illness the etiology was said to be much less clear than that of *dementia praecox*. Kraepelin proposed a genetically determined irritability of 'normal' affects, so that the psychosis itself emerged from certain predisposing 'basic states' (*Grundzustände*). The concept of degeneration was an important part of this hypothesis. In this period, Kraepelin integrated different types of circular or recurrent affective illness into the overarching concept of manic-depressive insanity (*Manisch-depressives Irresein*) (6th edition 1899).

Kraepelin's concept of paranoia was modified several times in this period. After the very broad concept of *Verrücktheit* of the early editions of *Psychiatry*, which was of restricted clinical use, he significantly narrowed it, especially in the 5th edition of 1896. Here, paranoia was defined as a severe and chronic delusional illness without constant alteration of personality and volition; the existence of abortive or benign cases was denied up to the 7th edition (1903/04). In the 8th edition (1915) this very rigid concept was broadened again, but not to such a degree as in the early versions. Kraepelin now accepted cases with low severity and a comparably good prognosis, but he maintained the strict separation of *dementia praecox* and paranoia.

In Kraepelin's view – typical of his way of thinking within the theoretical framework of degeneration theory – disorders of personality resulted from a circumscript retardation of psychological development. He argued that, since some patients with personality disorders reach a 'normal' or mature level of affective and cognitive functioning and some don't, it was not justified in this field to postulate clear-cut disease processes as, for example, in *dementia praecox*.

In his later period, 1916–26, Kraepelin reacted to several commentaries and criticisms of his nosology, for example, Alfred Erich Hoche's syndromatic theory and Ernst Kretschmer's suggestion to supplement the Kraepelinian system with a multidimensional approach. He moved toward an internal broadening of his system by reformulating his disease concept as discussed above; he combined a more differentiated view of pathogenesis and the role of individual psychological factors with a strong and unchanged position on the existence of 'natural disease entities.' Compared to this differentiation of the theoretical basis during these years, changes in clinical nosology were small.

Kraepelin and Twenty-First Century Psychiatry

Kraepelin's psychiatry became so influential during his lifetime, because it offered a pragmatical, clinical and prognosis-oriented nosology, developed by a self-confident author who focused on straightforward quantitative and naturalistic research methods. He claimed to abandon speculative aspects of psychiatry as far as was possible, although he himself did – unintentionally – 'import' a number of implicit theoretical and, in part, highly speculative aspects into psychiatry.

In the years after World War II, Kraepelinian ideas – and 'biological' concepts in general – lost much of their influence and were discussed mainly from the historical point of view. However, Kraepelin's concepts were 'rediscovered' in the 1960s and 1970s when 'biological psychiatry' – precursor of the neuroscience approach of our days – became the most influential (and most self-confident) field of psychiatric research. In particular, researchers and clinicians from the English-speaking countries viewed themselves as 'Neo-Kraepelinians' (Blashfield, 1984). But 'Neo-Kraepelinianism' was (and is) not a scientific theory in the strict sense. It has always been a heterogeneous set of concepts, trying to strengthen the basis for neurobiological research in clinical psychiatry. Central to it is the intention to identify the biological basis – the 'natural' basis, in Kraepelin's words – of mental disorders.

But these findings may well lead to a nosological system quite different from Kraepelin's, a topic which has attracted much interest in recent years. Many authors have postulated a 'denosologization' of psychiatric research, especially with regard to neurobiological research (Van Praag et al., 1987) or, more recently, a 'deconstruction' of diagnostic categories in psychiatry (Gaebel and Zielasek, 2008; Read et al., 2004; Van Os and Tamminga, 2007). The main idea here is to prevent nosological prejudices from hampering research by restricting the interpretation of data to the limits of 'classical' concepts, the most prominent of which being the Kraepelinian dichotomy of endogenous psychoses. Taking the recent literature into account, these authors have doubtlessly been right to predict that neurobiological findings will often fail to prove the traditional clinical boundaries. However, such an approach, although continuously modifying Kraepelinian nosology, does not stand in real contrast to his basic ideas. Kraepelin himself often stressed that all diagnostic criteria and categories were due to change according to the actual state of the art in psychiatric research – leaving, which is essential, his central postulate of the existence of 'natural disease entities' untouched.

'Neo-Kraepelinian' authors are – as was Kraepelin – at risk of overestimating the explanatory power of neurobiological findings, for example, by generally rendering biological data and criteria more reliable and valid than psychopathological or social ones. Nosological prejudices do, of course, exist in psychopathological and social sciences-approaches as well as in neurobiological ones. The essential point is that they always obstruct research, no matter what their theoretical underpinnings may be.

In the context of 'Neo-Kraepelinianism,' the operationalized diagnostic systems *ICD-10* and *DSM-IV* should be considered (APA, 2000; WHO, 1991). Their main impetus is to improve the reliability of psychiatric diagnoses by establishing clear diagnostic criteria and algorithms. They strongly favor descriptive methods by focusing on the behavioral level. Consequently they are skeptical against heuristic methods and try to avoid the interpretation of symptoms wherever possible. In addition, contrary to Kraepelin's nosological system which included a number of etiological hypotheses and, albeit mostly implicitly, epistemological presuppositions, operationalized diagnostic systems avoid etiological considerations, though not fully consequently for example, the ICD-10 groups F0 and F1 carry the main etiological factor in their very name (F0: 'Organic, including symptomatic, mental disorders;' F1: 'Mental and behavioral disorders due to psychoactive substance use'). It is a common misnomer to call this approach 'atheoretical' since no scientific concept can be 'atheoretical,' not in psychiatry and not in any other field. 'Etiologically neutral, where possible' would be much more appropriate. In spite of their theoretical differences, both Kraepelinian nosology and modern diagnostic systems run the risk of uncritically 'reifying' their constructs called 'diagnostic entities' ('reification,' derived from the Latin word res for thing or object ('Sache'), is an epistemological term meaning the identification of a concept with a 'real' entity which exists fully independently from the research and his conceptual framework, e.g., when the concept of schizophrenia is believed to be identical with or, at least, to prove the existence of a objectively (neurobiologically) detectable disease entity). This is why the authors of DSM-IV, for example, warn their users not to regard diagnostic categories as definite or 'natural' entities, not as 'natural kinds,' but as conventions which need further verification – or falsification. Consequently, operationalized diagnostic manuals are continuously modified according to new empirical evidence or conceptual developments (Möller, 2009).

In summary, Kraepelin's psychiatry was not only highly influential in his lifetime, but gained wide acceptance toward the end of the twentieth century, as the focus of psychiatric research again shifted to neurobiological topics. It is of crucial importance that present-day psychiatry – be it 'neo-Kraepelinian' or not – adopts a comprehensive view of Kraepelin's scientific work, embedded in a thorough knowledge of its complex conceptual history (Bennett and Hacker, 2003; Berrios and Hauser, 1988; Honnefelder and Schmidt, 2007; Hoff, 2010, 2012; Noll, 2011; Palm and Möller, 2011; Zivanovic and Nedic, 2012). Otherwise, as well as benefiting from Kraepelin's ideas, psychiatry will also be restricted by their conceptual limitations.

Abstract

The first section describes Kuhn's life and works. The second discusses Kuhn's theory of scientific development. This theory consists of a developmental scheme for the basic natural sciences that comprises the consecutive phases of prenormal, normal, and extraordinary science. The major differences between Kuhn's theory and the antecedent tradition are discussed, most notably Kuhn's insistence that scientific communities are the principal actors of scientific development. In the last section, Kuhn's influence on the social and behavioral sciences is discussed and assessed with special attention to his deep influence on the sociology of scientific knowledge.

Life and Works

Thomas S. Kuhn was born 18 July 1922 in Cincinnati, Ohio. He grew up in the State of New York and enrolled at Harvard University in 1940, where he majored in physics. Additionally, he attended philosophy courses and was particularly impressed by the theoretical philosophy of Immanuel Kant. In 1943, Kuhn earned a Bachelor's degree in physics from Harvard. During his graduate work in theoretical solid-state physics with John H. van Vleck (who later won a Nobel prize), James Conant, then president of Harvard, introduced him to the history of science. In 1947, while preparing a course on the development of mechanics prior to Galileo and puzzling over passages of Aristotle's physics, he discovered something that set the agenda of his further work. To understand the development of mechanics, Kuhn tried to find out which elements of modern mechanics were traceable back to Aristotle and which elements were first introduced in the sixteenth and seventeenth centuries. However, when Kuhn studied Aristotle with contemporary physical concepts in mind, much of Aristotle's physics, his conception of motion (kinēsis) in particular, appeared to be either false or even outright meaningless. Apparently, Galileo practically needed to start from scratch. However, this picture of Aristotelian physics, though prevalent in the first half of the twentieth century, seemed somewhat peculiar: Why would one of the greatest logicians of all time, an exceptional philosopher and otherwise perceptive scientist, who is widely regarded as one of the founders of biology, have been almost completely wrong in respect to physics? And why was Aristotelian physics, nevertheless, canonical for almost two millennia? These inconsistencies did not resolve until Kuhn managed to develop a different reading of Aristotle. He avoided the framework of modern physical concepts and tried to understand Aristotelian physics from an internal perspective. In other words, Kuhn developed a hermeneutical approach to the original texts which avoided semantic distortions through the import of modern scientific concepts as far as possible. By changing the ascribed meaning of some of the Aristotelian key concepts (in some cases only slightly and in others more intensively), a whole new world of physics became accessible, namely that of Aristotle and his contemporaries. In retrospect Kuhn described this episode as formative for his entire career in history and philosophy of science (Kuhn, 2000: pt. 3).

After completing his PhD in theoretical physics in 1949, Kuhn turned entirely to the history of science (motivated by a primary interest in philosophical questions though) where he began applying the insights he gained through his experience in Aristotelian physics. From 1948 to 1951, he was a Junior Fellow of the Harvard Society of Fellows where he met Willard Van Orman Quine, a then senior fellow in the society, and Karl R. Popper, who gave the James Lectures at Harvard in 1950. In this period Kuhn read gestalt psychology and Jean Piaget's work as well as Benjamin Lee Whorfs linguistic ideas, and he became acquainted with Ludwig Fleck's *Entstehung und Entwicklung einer wissenschaftlichen Tatsache* (*Genesis and Development of a Scientific Fact*), all of which promoted the development of his own ideas (Kuhn, 1962: preface; Kuhn, 2000: pt. 3). From 1951 to 1956 Kuhn was Assistant Professor for General Education and History of Science at Harvard. From 1956 to 1964, he was a member of the faculty of the University of California at Berkeley, mainly in the History of Science Department. During his years at Berkeley, academic discussion with Wittgenstein scholar Stanley Cavell, whom he already had met at Harvard, had a crucial impact on the development of Kuhn's nascent main work *The Structure of Scientific Revolutions* (*SSR*). In 1957, Kuhn published *The Copernican Revolution: Planetary Astronomy in the Development of Western Thought*, which became a very successful textbook. Kuhn spent the year 1958–59 as a Fellow at the Center for Advanced Study of the Behavioral Sciences in Stanford where he became aware of the different patterns typical of the interactions among natural scientists on the one hand, and among social scientists on the other. The difference typically concerns a broad consensus of natural scientists with respect to the foundations of their discipline, in contrast to social scientists who typically dispute them. This observation became very important when Kuhn wrote *SSR*. In 1960/1961, Kuhn finished the first draft of *SSR* and received important feedback from philosophers such as Paul Feyerabend (cf Hoyningen-Huene, 1995, 2006) and Ernest Nagel as well as physicist Pierre Noyes and historian John Heilbron, who was Kuhn's graduate student at that time. The completed book was published in 1962. *SSR* is the most widely read book ever

published in the history and philosophy of science, and it also had a tremendous impact in the social and behavioral sciences, most of all in the sociology of scientific knowledge. By now, more than 1 million copies of the book have been sold in English, and it has been translated into at least 26 languages. Its key term, paradigm, is now a household word. Some of its other central concepts like normal science, paradigm shift, or incommensurability are now commonly used in a large number of diverse disciplines. However, many of the interpretations of the book (or its parts) were vigorously rejected by Kuhn as deep misunderstandings of what he intended to say. In 1964, Kuhn joined Princeton University as a Professor of History of Science; he was also a member of the Institute of Advanced Study from 1972 to 1979. He met Carl Gustav Hempel, who was more open minded with respect to Kuhn's ideas than most contemporary philosophers, and became an important discussion partner for Kuhn during his time at Princeton.

Kuhn's historical work after *SSR* mainly concerned the genesis of quantum mechanics. *Sources for the History of Quantum Physics* (Kuhn et al., 1967) contains an inventory of relevant material including interviews with many of the contributors to quantum mechanics. *Black Body Theory and the Quantum Discontinuity, 1894–1912* (Kuhn, 1978) is a controversial narrative of the introduction of the quantum hypothesis. Some of Kuhn's papers both on the history and the philosophy of science are contained in his *The Essential Tension*, published in 1977. In 1979, he became Professor for Philosophy and History of Science at the Massachusetts Institute of Technology until he retired in 1991. From the 1980s on, Kuhn worked on a book whose final working title was *The Plurality of Worlds: An Evolutionary Theory of Scientific Development*. In this book, he tried to elucidate the foundations of scientific change through a new theory of meaning of empirical concepts, especially of taxonomic kind terms. Furthermore, he elaborated on the evolutionary metaphor for scientific development with which *SSR*'s last Chapter ended. Kuhn could not finish the book due to his death on 17 June 1996 in Cambridge, MA.

In 2000, *The Road since Structure* was published, which contains some of Kuhn's substantial philosophical papers between 1970 and 1993 and an extensive autobiographical interview from 1995. In summary, it can be stated that Kuhn is a distinguished historian of science and one of the most influential philosophers of science in the twentieth century. Even in 2007, 45 years after the publication of *SSR*, Kuhn belongs to the 40 most cited authors of books in the humanities and the social sciences (THE, 2009).

Kuhn's Theory of Scientific Development

Kuhn's main subject in the philosophy of science was a developmental scheme, or a schematic description, of scientific development that primarily concerned the basic (i.e., curiosity-driven) natural sciences. The intended description is schematic in the sense that it presents scientific development as a succession of different phases whose main features are independent of the specific subject matter of the respective science. For each one of these phases a specific mode of scientific practice is characteristic. This theory was first presented in *SSR* but was later refined in various respects.

The developmental scheme that Kuhn suggests should hold true with only minor variations for all basic scientific disciplines. It consists of the following: Before reaching maturity, nascent scientific fields are typically characterized by controversies between competing schools. Consensus lacks among the practitioners of the emerging field. Each one of these schools has a particular view of the respective research domain, and typically these views derive from extrascientific sources. This phase of scientific development can be referred to as 'prenormal.'

The competition among the schools could come to an end when one group produces an exemplary solution to a preeminent research problem with two characteristics: it is sufficiently unprecedented to attract the members of the other schools, and it is sufficiently open ended to leave enough interesting problems for further scientific work. These model solutions, for example, Lavoisier's oxygen theory or Maxwell's electrodynamics, are referred to as paradigms. They serve to guide research implicitly in the succeeding period called 'normal science.' When a particular science has reached its first normal science phase it is said to have matured.

Normal science is characterized by a broad consensus of the practitioners of the field on fundamental questions, and consequently, by a particular mode of research. This mode of research can be described by a five-dimensional analogy to puzzle solving where exemplars of puzzles include chess problems and crossword puzzles. The analogy concerns

1. The existence of regulations constraining acceptable approaches to and solutions of problems. In the case of science, these regulations are given only implicitly, namely as part and parcel of the paradigmatic solutions.
2. The expectation of the solubility of appropriately chosen problems. In the case of science, this expectation is fed by the conviction that the appropriateness of the paradigmatic solutions extends beyond the particular problems they are solutions of.
3. Missing intentions of fundamental innovation of the guiding regulations. In the case of science, normal science intends to exploit the cognitive potential intrinsic to the paradigmatic solutions, and does not intend to overturn them.
4. Absence of test or confirmation of the guiding regulations. In the case of science, this is due to the fact that in normal science, failure to solve a research problem is seen as a failure of the researcher and not of the regulations that guide research. Either the research problem was not chosen well or the researcher was unable to solve it despite its solubility.
5. Individual motivations: to prove oneself an expert puzzle solver. In the case of science, this is evidenced by the extremely elaborate system by which scientific achievements are rewarded (e.g., scientific prizes including the Nobel Prize, honorary degrees, invited lectures, nominations).

Normal science is always confronted with anomalies, that is, with phenomena or problems that behave contrary to the expectations supplied by the paradigm. Anomalies do not usually call the validity of the guiding regulations of normal

research into question. But under special circumstances they may, and then they become 'significant anomalies.' In such cases, the practice of science changes into 'extraordinary science' or 'science in crisis.' It aims at amending or even overthrowing the still binding regulations. Its research focuses on the significant anomalies and their context. Extraordinary science resembles prenormal science in that it tends to develop competing schools. However, it is more focused than prenormal science as all these different schools focus on the same set of significant anomalies and they all thrive to retain as much as possible from the earlier period of normal science. There are four possible ways in which extraordinary science can come to an end. (1) Eventually, it is possible to resolve the crisis triggering anomalies within the existing regulations. (2) The anomalies in question are disregarded if possible, that is, if the continuation of normal science is possible without interference. (3) Similarly to a speciation process in biology, a new scientific subfield is created in which the formerly troublesome cases are treated (Wray, 2011). (4) Research leads to a new paradigm that is accepted by the scientific community because it can lead to a new phase of normal science: the occurrence of a scientific revolution. Scientific revolutions in Kuhn's sense are thus "the tradition-shattering complements to the tradition–bound activity of normal science" (Kuhn, 1962: 6). Kuhn describes the features of scientific revolutions by characterizing the relation between successive traditions of normal science as 'incommensurable.'

In *SSR*, this incommensurability has three different aspects: First, through a scientific revolution, a change in the field of scientific problems that must be addressed by any theory of that domain occurs as well as a change in the field of problems that are legitimately addressed. Problems whose solutions are vitally important to the older tradition may be abandoned as obsolete or even unscientific; problems that did not exist, or whose solution was considered trivial, may gain extraordinary significance in the new tradition. Along with the problems, quite often the standards imposed upon scientifically admissible solutions change. For instance, in classical physics fundamental theories are required to be deterministic; this requirement vanishes with the quantum-mechanical revolution. A second aspect of Kuhn's (1962) incommensurability concept concerns scientific methods and concepts. After a revolution, many of the older concepts and methods are still used, but in slightly modified ways. The change of concepts discussed in *SSR* is of prime importance. It has an extensional and an intensional aspect. The extensional aspect consists of the movement of objects belonging to the extension of one concept into the extension of another concept, the two concepts being mutually exclusive. The striking example that Kuhn uses in *SSR* is the change of the concept of a planet in the Copernican revolution. After the revolution, the earth, for instance, is a planet, whereas the sun and the moon are not planets anymore. The intensional aspect of the change of concepts consists of a change of meaning of the respective concepts. This is the case since the properties of the objects that are subsumed under these concepts change. As the third and most fundamental aspect of incommensurability, Kuhn claims in *SSR* that scientists belonging to different paradigms conduct their research in different worlds. But what does it mean to say that the world changes with a revolution? This question is not answered in *SSR*, although Kuhn has clearly seen its urgency there.

To understand this aspect of Kuhn's theory, it is important to distinguish between two meanings of the term 'world' in Kuhn's philosophy, namely the phenomenal world and the world in-itself. It is the phenomenological world to which we actually have access in everyday life or in science. We can perceive and describe such a world, and in such a world there are octopuses, lecture halls, and electrons, for example. Such a world has a certain conceptual structure, for instance the aforementioned categories. Kuhn supposes that these concepts are of human origin, that is, we impose a structure on the world by means of these concepts, instead of just reading off these concepts from the world itself, as a more familiar (realist) story wants us to believe. Although it is not possible to impose any and every structure on the world, clearly more than just one is possible, which implies a certain degree of historical contingency of these structures. This is illustrated by the historical change of these conceptual structures that are embedded in paradigms. As a consequence, paradigms are constitutive of a perceptually and conceptually subdivided world. In other words, the subjects of knowledge contribute to the constitution of the objects of knowledge (by means of paradigms) insofar as they structure the world of these objects.

The second sense of the term 'world' in *SSR* is obtained by asking what is left if one subtracts all these human (subject-sided) contributions, all this perceptual and conceptual structuring from the world in the first sense. Then, one is left with a world that is completely independent from our perceptions and conceptions, a world – as one might say – that is purely object-sided. But we have, according to Kuhn, no access whatsoever to this purely object-sided world. According to Kuhn, what we, or a particular scientific community, describes as reality is a – but not the only possible – phenomenal world. Due to the historical change of these worlds, Kuhn's theory has sometimes been described as 'Kant on wheels.' Note, however, that numerous philosophers of science are extremely skeptical about these apparently idealist elements in Kuhn's philosophy and reject the cogency of this line of argument (e.g., Godfrey-Smith, 2003; Preston, 2008).

Due to incommensurability, we must, according to Kuhn, rethink the concept of scientific progress in the natural sciences. First, scientific progress is not cumulative, due to conceptual changes during revolutions. Cumulativity implies that something that is a part of science at some point in time will, neglecting small corrections, remain a part of science forever. However, the conceptual changes that occur during revolutions are much more than slight corrections of the existing body of knowledge. They amount to a sometimes far-reaching conceptual reorganization, and typically to a changed ontological perspective. This holds true in spite of the fact that very often much of the older knowledge is retained, especially for practical applications, and that, in the case of quantitative theories, limiting relations exist between the older and the newer theories. Furthermore, Kuhn denies that scientific progress is an approach to truth. Instead of conceiving scientific progress as a teleological process, that is, one that is goal directed, we should think of scientific

progress in an analogous way as Darwinian evolutionary theory conceives of evolution (Reydon and Hoyningen-Huene, 2010). Darwinian evolutionary theory states that there is no goal of evolution toward which it is directed. In a similar way, in scientific development there is no 'set goal' which would be 'a permanent fixed scientific truth' that science approaches (Kuhn, 1962: 173). However, Kuhn stresses that this does not imply at all that there is no progress in the sciences. There is progress in the sciences, though not in the form of an approximation to truth. Rather, there is progress in the form of 'an increase in articulation and specialization' of scientific knowledge (Kuhn, 1962: 172). Therefore, the widespread characterization of Kuhn's theory as relativist is simply false.

There are several breaks between Kuhn's theory and the previous tradition in the philosophy of science, some of which explain the extraordinary resonance his theory found in the social and behavioral sciences. Seven of them will be discussed briefly. The first is Kuhn's altered view of scientific progress that has just been given. Second, this view implies the untenability of forms of realism which assert that science at least approximately describes what is really 'out there,' independently of any observer. Instead, theories describe the world in terms of concepts that are historically contingent (but not arbitrary!) and which may change in the future. Third, because of this change of basic scientific concepts through revolutions, the classical conception of reductionism is also hardly tenable. In this classical conception, the redefinition of the concepts of the reduced theory by means of the concepts of the reducing theory played a key role. But if incommensurability prevails, some of the required redefinitions are impossible because of meaning shifts. Fourth, many of *SSR*'s assertions stood in marked opposition to Popper's critical rationalism. For Popper, good science depends on the constant questioning of all issues in a scientific field. Kuhn's normal science, as seen from Popper's perspective, is therefore bad science since it is not continuously directed toward critically testing the guiding regulations. Instead, some anomalies are not even pursued, but are ignored or even pushed aside. Alternatives to the paradigmatic framework are also typically ignored. Yet in Kuhn's view, critical evaluation of fundamental theories is restricted to the periods of extraordinary science, and even then, scientific practice is not simply an attempt to falsify theories by confronting them with observational statements about nature. Rather, theory evaluation is a comparative procedure in which at least two theories are assessed with respect to their scientific potential. Thus, according to Kuhn, theory falsification as described by Popper is a stereotype that does not occur in the actual history of science. A fifth break results from Kuhn's concern for the actual history of science and its assigned role in philosophy of science. Kuhn argues that the abovementioned historical–hermeneutical approach to the history of science can provide us with important data that a reasonable philosophy of science should incorporate. This is frequently referred to as the 'historical turn in philosophy of science.' Pre-Kuhnian philosophy of science, in contrast, unknowingly depends on a stereotypic picture of scientific development, which has its origin in a presentist interpretation of past scientific theories via modern scientific concepts. A sixth consequence of Kuhn's theory is the abolishment of the idea that science is determined by logic and observational data alone, or by the scientific method, as construed as a set of rigorous rules. This idea has dominated the understanding of modern science from its very beginning. According to Kuhn, however, exemplary problem solutions guide scientific research in its normal phase. Their cognitive potential for research is not exploited by explicit (or fully explicable) rules, but rather by implicit analogies. New problems are identified in the light of solved ones, and new solutions are judged as legitimate in a similar manner.

Finally, and most importantly in our context, the principal agents of science according to Kuhn are communities, not individuals. In the philosophy of science tradition before Kuhn, no one questioned the identity of the principle agent of science. Though armed with the distinction between individuals and communities, it is obvious that in the older tradition, the individual scientist was seen as the principal actor. The possibility of two scientists rationally disagreeing was not permitted, nor were there discussions about the gradual formation of scientific consensus out of disagreement, or of the development of disagreement from a previously established consensus. In other words, scientific communities were barely present in this discussion. Science was primarily seen as a one-person game, but for Kuhn it is, at its heart, a social enterprise. It is communities who are the ultimate evaluators of knowledge claims. It is communities who ultimately decide between competing theories and their associated modes of research, and it is communities who are seen by themselves and by others as responsible for some domain of scientific knowledge. Kuhn, therefore, repeatedly refers to the 'sociological base of (his) position' (for references, see Hoyningen-Huene, 1993), but at the same time, he insists that this fact does not invalidate the essential epistemological component of his theory, that is, its normative element. How is this to be understood?

Kuhn characterizes scientific communities by the values they hold. Typically, these values comprise accuracy, scope, consistency, fruitfulness, and explanatory power, among others. These values are instrumental in the evaluation of the application of theories and, partly derivatively, in the evaluation of the theories themselves. However, these communal values are not so strictly defined that each member of the community reaches exactly the same evaluation in a concrete case of application. Individuals may differ in the relative weight they attribute to these values as well as in the specific articulation of any one of them. Yet in normal science, these differences typically do not become apparent; they remain latent. However, with the advent of significant anomalies, these latent differences between scientists belonging to the same community may become manifest due to different evaluations of the anomalies, resulting in dissent. The dissent may continue with respect to the different candidates proposed to resolve the crisis. A new consensus about some theory and its ability to solve outstanding problems can only emerge if, and when, (almost) all members of the community prefer this theory over its competitors, although their individual differences with respect to the values have not fully disappeared. Thus, during crisis resolution, the individual differences of the members of the community become insignificant: it is the communal core of the values that prompts the choice of the new paradigmatic theory. Thus, the choice of the new theory is essentially an event that must be described in sociological terms,

as opposed to psychological ones. However, the normative dimension of theory choice has not disappeared. The reasons for the choice may still be normatively evaluated: scientific values are an essential part of the reasons for choosing some theory. They are good reasons if they promote the aims of science, that is, the comprehensive and systematic description and explanation of nature. This does apply to the values mentioned above (i.e., accuracy, fruitfulness, consistency, and the like) (Hoyningen-Huene, 1992).

Kuhn's Impact on the Behavioral and Social Sciences

Kuhn's work is extremely widely received in the social and behavioral sciences. Before Kuhn, mainstream social science adopted a picture of the natural sciences that was based mainly on logical empiricism, and many social scientists attempted to assimilate their disciplines to that picture. However, success was limited. Neither the predictive nor the explanatory power of a natural science like physics could be achieved. In addition, methodological controversy did not cease to exist even if in some field a particular school became dominant for some period. In this situation, the alternative view of the natural sciences that Kuhn offered also seemed to suggest, as a corollary, a different view of the social sciences. More specifically, as Kuhn incorporated elements in his description of the natural sciences which had been barred by the earlier tradition in the name of the objectivity of science, such as group processes and the like, the difference between the natural and the social sciences seemed to have decreased. In this way, the already comparatively high interest that social scientists have in the philosophy of science, given the epistemologically insecure status of their disciplines, became even more intense in the case of Kuhn's philosophy. At least to some authors, Kuhn seemed to suggest a new understanding of the social sciences.

Three general facts about the reception of Kuhn's work in the social and behavioral sciences are striking. First, the reception was by and large uncritical, and in many cases very superficial. For example, there are literally hundreds of articles in which reference to Kuhn appears to be a purely rhetorical device, making no substantial point. Second, Kuhn's developmental model was intended to apply only to the basic disciplines of the natural sciences. Kuhn says very little about the social sciences, basically only that they are typically in the preparadigmatic state (Kuhn, 1962, 1977). This did not prevent many social and behavioral scientists from applying parts of Kuhn's theory to different aspects of their disciplines. Third, Kuhn's ideas have been used for the most diverse purposes. On the basis of his work, even outright contradictory assertions have been made. This is partly due to the fact that Kuhn's writings, especially *SSR*, have resulted in several very different interpretations, which derives from the inner tensions, ambiguities, and metaphors that his works contains. In particular, Kuhn's evaluation of the rationality of science appeared as highly ambivalent, and his use of the paradigm concept seemed at times to cover just about everything that scientists deal with. Thus, Kuhn's texts appear to have a high degree of plasticity, a fact that has been subsequently deplored by its author. Only a very close and patient reading of the texts can reduce this plasticity. On top of the plasticity of Kuhn's texts, social scientists have been seduced to read many things into Kuhn's work due to their own agendas. Thus, many of the claims in the literature about what Kuhn does or does not support are not actually contained in Kuhn's texts.

The predominant use of Kuhn's work in the social and behavioral sciences has concerned the current status of some discipline or its history. Is the discipline still in its prenormal state or does it already have a paradigm? In other words, is it a 'mature' science that has reached the state of normal science? Has it had paradigms in the past? Are the changes that the discipline experienced in the past Kuhnian revolutions? Could competing theories, say in sociology or political science, be described as incommensurable? Or are the social sciences fundamentally different from the natural sciences in that they are 'multiple paradigm sciences?' As mentioned above, these questions received the most diverse answers by different authors. Elements from Kuhn's theory were used by some to defend mainstream social science, and by others to develop a critical attitude toward it, or to defend or attack alternatives. Some authors tried to show that on Kuhnian terms, a given social science closely resembles a natural science, whereas others tried to demonstrate the opposite, and so on. No consensus has been reached in any of the social or behavioral sciences about these and other related questions.

Regarding the history of science, there is, perhaps surprisingly, not much of a reception of Kuhn's *meta*-historical work. This may be partly due to the same reasons that Kuhn did not apply his characteristic concepts (like paradigm, normal science) to his own historical work. Historians often try to avoid heavily theory-laden concepts when doing historical work due to the imminent distortions of what can be obtained from the sources themselves. In addition, historians in the second half of the twentieth century have typically been quite critical about any generalizations on the course of history (such as a developmental scheme).

In the sociology of scientific knowledge, however, Kuhn's impact has been tremendous. Pre-Kuhnian sociology of science either discussed the social structure of science or the impact of science upon society. The scientific content seemed to lie entirely outside the scope of sociology because of the purported objectivity of science, which precluded any direct social contingency. The most relevant sociological question asked with respect to scientific knowledge was 'What are the social conditions of a scientific community that are conducive to the production of such knowledge?' Answers to this question typically consisted of the description of a purportedly universal value system which holds true in scientific communities. This value system was seen as virtually guaranteeing the desired outcome of the activities of the community's members. However, with the advent of Kuhn's work, this view was challenged in various respects. The production of scientific knowledge now seemed not at all determined by time-independent, universal methodological rules. Instead of binding rules, research is guided by paradigms that include values that only influence, but do not determine scientific behavior. In addition, individual members of the community differ in their specific assimilation of the communal values and their relative weights. In other words, scientific knowledge now seemed socially contingent which licenses and even appears to demand sociological analysis. Various schools developed

analytical tools for this purpose, and a great many case studies of contemporary and past science were performed in the emerging field of Science and Technology Studies (STS). Typically, the content of science was now seen as the result of negotiations among scientists in which human interests of a personal or political nature, or social positions and power relations within scientific communities, played an important, and sometimes even decisive, role. Along these social constructivist lines, scientific knowledge can no longer be seen as objective in the traditional sense of the term. Due to an intense debate within sociology and interventions mainly from philosophers, these positions showed rapid development that continues until today. It should be noted, however, that despite all of the changes in these positions, Kuhn himself remained extremely skeptical of them. In his view, the epistemological dimension of scientific knowledge, that is, the possibility of its normative evaluation from an internal perspective, must be an essential part of an integrated image of science. It is only in this manner that the object-sided aspects of experience, which constrain the possibility space for scientific theories, can be properly taken into consideration. This aspect of Kuhn's theory had been entirely dismissed by many sociologists of scientific knowledge (Kuhn, 1991, 1992).

Abstract

Approaching the centennial of Malinowski's initial fieldwork and writing about the kula ring in southeastern Papua New Guinea, this article reviews the history of research on the institution, describes its fundamental forms and outlines some of the questions that have been and will be addressed to the institution as a new generation of scholars begin to redefine this classic region in the history of anthropology.

First set out in detail in Malinowski's classic *Argonauts of the Western Pacific* (1922), the 'kula ring' – a translocal, long distance exchange network connecting islands off the southeast coast of Papua New Guinea (**Figure 1**) – remains a classic ethnographic reference point for the study of non-Western exchange practices and the development of exchange theory. Malinowski's work was followed by more limited contributions by Fortune (1932), Roheim (1950), and Belshaw (1955), but it was not until the late 1960s and 1970s when new field research yielding significant publications on kula was carried out (see Leach and Leach, 1983). Some of those first returnees continue to publish on the institution (e.g., Damon, 2002), and a new set of scholars are examining the region with fresh eyes (beginning with Kuehling, 2005). Archaeological research provisionally locates the region in the larger context of the human occupation of the Pacific in general and the Austronesian expansion in particular (Bickler, 2006; Ambrose et al., 2012). Today the region is once again being subjected to Western-inspired resource extraction and incursion analogous to that which occurred during the transition from the nineteenth to the twentieth century, yet local people now occupy most modern state offices, diesel boats and

Figure 1 The kula ring. Standard English names are given in parentheses.

fiberglass dinghies motored with outboards facilitate much of the interisland communication, and most islands have vastly expanded populations. However, the kula institution remains robust, absorbing as much of the new as it is being absorbed by it. This article explains the key features of kula, updating Malinowski's account where necessary on the basis of the more recent work and modifying some common oversimplifications; in conclusion, it comments briefly on anthropological approaches to kula.

Some Defining Features of Present-Day Kula

The exchange of white (*Conus*) armshells and red (*Spondylus* or *Chama*)-shell necklaces in opposite directions around the islands centers the modern kula exchange (**Figure 1**). The valuables are gendered, all are qualitatively graded but only middle and upper ranked shells have personal names. They circulate in formal relationships denoted by a word which may be translated as 'path,' 'way,' or even 'meaning,' ked/keda/eda and cognates. There are other kinds of kula media (see Section Adjustment of Some Common Oversimplifications of Kula), one of which, pig tusks, no longer circulates but for some reason became collected by the hundreds on Goodenough Island. However, only the two shell types currently circle the region establishing its basic sociogeography. Kula transactors, however, should exchange directly in a limited sector with partners or potential partners in participant communities on either side of them (although illicit bypassing occurs). Only occasionally and usually just with the very largest valuables do people know exactly how specific transects close. The problem the institution addresses is the rank of its transactors. Their primary aim is to increase their ranks by means of the ranked shell exchanges. Rank is usually stated as the height or visibility of a person's name. Transactors obtain shells of one category on visits to partners in one direction and later give them to their own visitors from the opposite kula direction. Typically, these practices engage long-term debt involving a year or much more between a gift and its equivalent repayment. A major transaction with multiple, additional shell exchanges pinned to its passage may go on for years, and big men work toward this result, often eschewing exact returns in order to keep debts, relationships, active. Nevertheless, less prestigious exchanges may occasionally be completed with a visitor who brings the appropriate type of shell for immediate exchange, thus avoiding the risks of default inherent in time and distance. Defaults, however, are common, and many a high name has tumbled into obscurity.

Although kula participants are primarily men, recent research points to the contemporary importance of women all across Muyuw (Woodlark Island), in the Bwanabwana region (Macintyre, 1983a), and Dobu (J. Leach in Leach and Leach, 1983, p. 17). Nevertheless, women participants rarely sail on kula voyages and it is very rare for a woman to become as significant in the institution as some men regularly do.

Research from the 1970s has also revealed a crucial type of shell ownership not noted by Malinowski (but probably operative in his time) called 'kitoum/kitomu' (or cognates). It is fundamental to the *modus operandi* of kula. A shell's first owner is its maker. Owners may do as they wish with their kitoum shells, keeping them for strategic use in the main kula competition; turning them into significant quantities of food, pigs, magic, or cash; using them to pay off another person's kula debt, and so acquire the relationship that debt made; or, on some islands, using them to replace people who may have been killed by witchcraft or other actions. On some islands, men formally have to replace their deceased wives with one or more kitoum, if the woman has moved from her village to his. Among the more intense actors within particular locales, these transfers become purposely enmeshed in marriage and kinship, and so intergenerational relationships become part of the category's significance. A shell transferred as a kitoum becomes another person's kitoum, thus overriding a valuable's understanding as an armshell or necklace, and in isolated cases, a valuable may even reverse customary shell directionality (counterclockwise for armshells, clockwise for necklaces). If used in normal kula exchange, when one gives away one's kitoum its equivalent return becomes, on receipt, the replacement for the original kitoum, the prior shell becoming the kitoum of the equivalent's donor. Thus particular kitoum represents powers or capacities that may change form from one thing to another, from an armshell to a necklace, armshell/kitoum to a pig, boat, or one clan or subclan's possession to another's (Damon in Leach and Leach, 1983; Munn, 1977, 1986; Weiner, 1988, 1992 cf also Godelier, 1996, pp. 90–91). Kitoum shells, empty of prior obligations, may be said to provide an element of freedom in transactions and so variously aid owners in the building of their positions. They anchor a kind of capital circuit.

Adjustment of Some Common Oversimplifications of Kula

Following Malinowski's emphasis, a common assumption is that modern kula entails a ritual exchange of just the two types of shell set apart as a system from trade with other nonritual goods (see Section Anthropological Approaches to Kula). But a variety of evidence indicates that such a sharp line cannot be drawn between different items produced or acquired for exchange. For instance, in Bwanabwana and Muyuw (**Figure 1**), pigs are intrinsic to kula (there called 'kune') although they obviously do not circulate around the whole ring (e.g., Macintyre, 1983a, pp. 105–106). Overseas directional transactions of Gawan-built canoes can also be described as 'kula-ing' one's canoe. Armshells from southern canoe recipients become the canoe producers' kitoum; with the exchange finished, canoes are transferred from their makers by means of shell valuables (Munn, 1986). Moreover, the institution is the ultimate expression of regional interdependency which, if not always visible, becomes clear in crisis contexts. The 1997–98 extreme El Nino Southern Oscillation first created a desperate situation on the small islands between Muyuw and the Trobriands, then eventuated a massive movement of yams, as food and seed, from Muyuw to Gawa, Kweywata, and Iwa. That movement of resources swamped the usual patterns of reciprocity in the region (Iwa, for example, is packed with various nut trees which it regularly gives as gifts to other islanders). Participants explained this situation by ignoring

the lower-tiered practices. They couched their actions in the requirements of the kula exchange: without that movement of food and seed stock Iwa would cease playing its role in the chained relational network that is the first condition of the region (see Damon, 2008).

If kula media are not as exclusive as sometimes supposed, so also the circulation of the shells themselves is not exclusive to Massim islands participating in the ring: other islands make use of these shells, leaking them into and draining them out of the kula region, thus affecting kula circulation. Indeed, as Malinowski reported, a source of the necklaces (Rossel Island) is itself far south of the ring. Until the 1960s, Maylu people from along the southeastern coast of Papua New Guinea used to sail deep into the northern reaches of the ring to dive for conus shells for their own different use of the valuables. People from Muyuw, who directed them to their reefs, remember this as a time and context for an entirely different exchange of regionally defined products compared to those that regularly circulated within the region as defined by the reciprocal exchange of armshells for necklaces. Kula is in this sense an open not a closed system, and thus very much like Lévi-Strauss's model of generalized exchange (Levi-Strauss, 1969, see also Weiner, 1976).

Neither is kula static. In its present form, which can be tentatively dated to *c.*1400, it is a modern development undoubtedly affected by British colonization. One key change has been the widening of participation in kula. Formerly confined to men of influence, it may be argued that the kula effloresced, becoming increasingly 'democratized' as endemic warfare gave way to British 'pacification' (Macintyre, 1983b; Young, 1983). Of course change is ongoing; for instance, in the 1990s the increased use of Western boats by Bwanabwanans was reducing the southward extension of canoe transactions, thus negatively affecting Gawan acquisitions of kitoum from canoes. As of 2012, the last two-way voyage of an eastern kula ring large kula canoe (anageg) was in 2002. The canoe builders on Gawa, Kweywata, and Yanaba are trying to adapt a new canoe structure to their old role in the network of islands. Interestingly, this new form comes out of the very southeastern appendage of the region replicating the myth if not the reality of the 'original' anageg form, which, while largely built in Gawa, Kweywata, and to a lesser extent Yanaba, most people consider it to stem from the Sudest (Vanatinai) Island area.

At another level, change is inherent in the way individual kula paths and routings are constituted. A path of partners is initiated and maintained only through the passage of shells: without shells a path disappears. *Pace* Malinowski (1922, p. 83), partnerships are not necessarily 'permanent.' In a politics that entails the constant testing of trust and building of productive support systems, shifting personal relations alters paths across the ring. Nor are routes between communities fixed. Over time kula's competitive practices can yield not just individual path alterations, but also alterations in routes. Thus by the 1970s Duau (north-east Normanby) villages no longer did much kula directly with Bwanabwana: new southern coastal villages of people from the interior inserted themselves into the route (Thune in Leach and Leach, 1983, p. 352). In the 1970s the hierarchy of Trobriand chiefs played miniscule roles in the kula; that is not true now since, for example, virtually every significant kula actor in Muyuw, in the northeast sector of the ring, has or desires to have a relationship with the Trobriand paramount chief, Pulayasi.

This dynamic view of kula also illuminates noncircular aspects of its sociogeography. A path may never attain circularity because closure can be produced only by making reliable connections via the passage of shells. Although participants invariably describe the total system by means of the clockwise and counterclockwise movement of the two valuables, only the very highest ranked valuables occasionally travel in closing circles. Two that were said to be doing that in the 1970s and 1980s, the armshell Klibulouboul and necklace Senubet, were not so traveling over the last 15 years. Most valuables remain organized by unified lines of intentionality for only a few moves before being defined by different motives. Understanding, influencing, and reacting to diverse intentions are in fact in the center of the contest that is the kula.

Just as kula participation and paths are subject to change, so also is the larger organization marked by variability throughout the ring. Without question kula shells act as a kind of currency and so play a profound mediating role. But whereas many currency systems operate by means of an absolute equivalency, a single hierarchizing value, and although one may view the kitoum category in this guise, the fundamental structure of the institution forms patterns of discontinuity. The complementary differences between the two shell types, armshell and necklace, in many parts of the region phrased as male and female, respectively, symbolize if not generate an elaboration of differences. The system runs on niches, minor and large productive differences between islands and parts of islands. Additionally, there are different articulations with marital and other domestic exchanges. In Bwanabwana, kula is not sharply separable from marriage exchanges, but in the Trobriands the two are kept apart (Macintyre, 1983a; Weiner in Leach and Leach, 1983). Elsewhere, articulations vary. Gawan men take shells from their kula paths to give to affines for the latter's paths; shell returns ideally go back to donors and the original paths (Munn, 1986). But on Vakuta, shells taken off paths for affinal recipients in return for gifts of pigs become these affines' kitoum, even though they may not be the donors' kitoum (Campbell in Leach and Leach, 1983, pp. 206–207); presumably donors must find path replacements elsewhere. These sorts of local differences, among many others, have ripple effects on translocal shell movements (cf also Wagner, 1989, p. 270; Persson, 1999). These facts are not just the result of analytical distance. Since socially significant numbers of people travel from one island to another consciousness of cultural variation is intrinsic to the social order, and in the experience of some of the recent ethnographers at least, it is evident that communities regularly select particularly smart youths for significant interisland experience. In the 1970s, some of the elders running the system in its northeast corner worried that the relatively recent expansion of the United Methodist Church, due to a particularly active SIL (Summer Institute of Linguistics) missionary Bible translator, was pulling away so many of the smart younger men that in the near future there would not be enough shrewd people to keep the system intact. In 2012, one of those people who had been pulled

away, but who had now retired from the Church, agreed that this was a problem.

Anthropological Approaches to Kula

Serious focus upon kula first emerged within two formative studies of anthropological thinking on exchange: Malinowski's (1922) first major work developing his use-oriented functionalism and Mauss' (1950) classic essay on the gift. Basic problems posed by typical, pre-1970s kula commentaries drew on Malinowski's questionable dichotomy between kula as a ceremonial practice involving the transaction of 'useless' things and the economic trade of 'useful' things (for a brief critique see Young, 1983, p. 8). The distinction between ceremonial (kula) and nonceremonial trade was also the prototype for the later development of more complex models of economies with multiple separate 'exchange spheres' (cf Firth, 1957, p. 218).

The same Western economic dualism framed the search for some single explanatory function, or 'purpose' of kula such as 'prestige competition' (J.W. Leach in Leach and Leach, 1983, pp. 5–6). In particular, it fueled the concern with finding an economic function for kula by putting it in the service of the 'useful' commerce – for instance, as establishing 'the peace of the market' enabling utilities to circulate (Singh Uberoi, 1962, p. 148; see Macintyre's 1983b critique of the association of kula with peacemaking). The period's most serious reexamination combined some of these ideas in a more broadly based structural–functional study (Singh Uberoi, 1962) which viewed Trobriand kula as a sociopolitical practice periodically releasing men from internal descent group relations to establish interisland bonds.

It is, however, Mauss' concerns that pervade contemporary kula analyses. Mauss situated kula in a theory of moral–juridical contract empowered by bonds between persons and things. His attention to the cultural symbolism and ontology of 'person–thing' relations in gift exchange (rather than simply to exchange relations between things, as in the 'exchange spheres' model) has been influential in recent exchange and kula studies. Godelier (1996 [1999]) synthesizes much of the 1970–90s word derived from Mauss. Mauss' contrast between 'archaic' gift exchange and the modern Western market-based system is also one root of current arguments involving another dualism, that of 'gift' and 'commodity' exchange. Kula figures prominently in these arguments – for instance, in Gregory's (1982) widely cited, if problematic, model of gift exchange as the transaction of 'inalienable objects' in contrast to the 'alienable objects' of commodity exchange. Some would say that the dynamics of kitoum may be expressed in terms of alienated powers, and if so this would suggest the difficulties of applying this dichotomous framework to kula. This, however, may be misreading what is intended by the discussion of alienation. That idea is not so much about people being separated from objects as it is about being separated from their capacities, their powers. In the kula, people are separated from their kitoum, their boats, their pigs, their brothers, sisters, and children. But when these disjunctions find their replacements in kitoum, the absolute pivots of kula exchange, their powers are not so much lost as transformed into other modalities. It is no wonder then that kula actors marvel about where 'profit' comes from in the Western system that now encompasses them. Many of these are people who have the cultural memory of at least 100 years of Western intrusion and who can recount this time period's fantastic transformation in wealth, that is capital, the difference between the picks and shovels of 1910 and Caterpillar Wheel Loaders of today, and the tankers and other massive steel ships that traverse this region to and fro between Indonesian oil and Australian twenty-first-century mechanization. While the institution condenses many features of Indo-Pacific societies scholars will contemplate well into the future, it also continues to hold up a mirror for Western practices long ago anticipated in Malinowski's first masterpiece.

No single orientation dominates contemporary kula studies. Rather, kula has been subject to varied forms of rethinking: for example, in terms of a Marxian concern with grounding circulation in production and labor value (Damon, 1980), a symbolic formulation of action, spacetime, and value (Munn in Leach and Leach, 1983; Munn, 1986), or gendered models of power and social reproduction (Weiner, 1992). Persson's (1999), following to some extent Damon (1990), detailed a comparison of selected Massim societies, and thus approached kula through the study of regional variation (see also Damon, 2005). Among the analyses that the future foretells are a richer understanding of the anthropogenic nature of the region's ecology and an understanding that will embed its cultural forms in the social variation evident from at least Bali to West and the sacrificial ranking systems that created what we know of Polynesian sociality to the east. Since its introduction into anthropology at the beginning of the twentieth century, kula has been a sounding board for anthropological issues and continues to be so as a new set of scholars take its bearing amid the classics in a new century.

Kuznets Curves

Tommaso Luzzati, Università di Pisa, Pisa, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explains what the Environmental Kuznets Curve is, how was it born, what are its theoretical underpinnings, and the findings of the empirical literature. It discusses the main weaknesses of the debate, also highlighting an inconsistency that has been ignored so far. This article is not a survey of the literature. Rather, it attempts to provide a systematic and original presentation of (hopefully) all the ingredients of a fairy tale, telling us that economic growth will eventually result in environmental improvement.

What Is the EKC?

"Does inequality in the distribution of income increase or decrease in the course of a country's economic growth?" is one of the main questions of the presidential address given in 1954 by Simon Kuznets at the 67th annual meeting of the American Economic Review (Kuznets, 1955, p. 1). His answer was that inequality might increase with per capita income at an early stage of economic development and eventually decrease as income continues to grow. In graphical terms, the relationship between inequality and real per capita income might have a 'bell-shaped' or 'inverted-U' curve. When reading the article, one realizes how cautious Kuznets was in suggesting this relationship. The scarcity of data led him to define the trends he found as "perilously close to pure guesswork," and to affirm that his articulated "attempt to explain these dimly discernible trends may surely seem foolhardy" (Kuznets, 1955, p. 5), and to describe his paper as "perhaps 5 percent of empirical information and 95 percent speculation" (Kuznets, 1955, p. 26). Actually, his main goal was to stimulate research in a topic that he viewed as "central to much of economic analysis and thinking" (Kuznets, 1955, p. 26) and calling "for a shift from market economics to political and social economy" (Kuznets, 1955, p. 28).

The prudence used by Kuznets did not characterize much of the literature that, beginning in the early 1990s, looked for an inverted-U relationship between various forms of environmental pressures/states and income per capita; that is, a relationship predicting the economic growth harms the environment in the early stage of economic development and improves it after a given level in per capita income is reached (see **Figure 1**). This relationship was named after Kuznets as the Environmental Kuznets Curve. Dasgupta S. et al. (2002, p. 147) attributed the coining of the term to Grossman and Krueger (1993). Actually, Grossman and Krueger did not use the term EKC in the 1993 paper nor in its preliminary version, the NBER working paper appeared in 1991. Panayotou (1993) was the first to use this term in a published paper. The EKC hypothesis was rapidly taken by many economists as a stylized fact—For instance, at the very beginning of the debate, Panayotou (1993: Preface) affirmed that "an environmental Kuznets curve is an empirical reality" and Selden and Song (1994, p. 147) wrote that "there is an emerging consensus that at least some forms of pollution exhibit inverted-U, or 'Kuznets' relationships with economic development." The EKC was used to maintain that (market driven) economic growth is needed for sustainability. Beckerman (1992, p. 491), in an often quoted sentence, wrote that "in the end the best – and probably the only – way to attain a decent environment in most countries is to become rich." Clearly, the EKC hypothesis can be traced back to the controversy on the environmental limits to economic growth started by the famous Club of Rome report (Meadows et al., 1972) that showed how unregulated growth could become a major threat to human welfare. The policy orientation of the EKC debate is expressed well by the quote of a paper by Grossman and Krueger (1995, p. 353) who commenced by asking "Will continued economic growth bring ever greater harm to the earth's environment? Or do increases in income and wealth sow the seeds for the amelioration of ecological problems?"

Figure 1 Environmental Kuznets curve.

Grossman and Krueger (1991) are actually those who started the EKC literature with a paper about the environmental impacts of the North American Free Trade Agreement (NAFTA) agreement, closely followed by other seminal contributions, particularly Shafik and Bandyopadhyay (1992), Hettige et al. (1992), Holtz-Eakin and Selden (1992), Panayotou (1993), Selden and Song (1994), and Grossman and Krueger (1995). The topic gained immediate popularity and, since then, a huge number of articles have been published. One of the reasons for this success was that, since the 1990s, large datasets with environmental indicators became eventually available, despite the urgent need for them was already advocated in the 1950s by the pioneering contributions on enviromental degradation of the German institutional economist K.W.Kapp. (see Luzzati, 2009).

Theoretical Underpinnings for a Bell-Shaped Relationship between Per Capita Income and Environmental Degradation

(Environmental degradation and quality are thought by economists as latent constructs. Empirical analyses attempted to capture them by using indicators of environmental pressure and, less often, state. It has to be emphasized that also income 'inequality' in the original Kuznets curve can be captured by different indicators. Its meaning, however, is much more precise, than that of the vague idea of environmental quality.) Following Grossman and Krueger (1991), economic growth is usually thought to affect environmental quality through the following effects: 'scale,' 'composition,' and 'technique.' 'Scale' refers to the *size* of an economy and has an adverse effect on environmental quality since increasing output requires more input and involves more emissions and waste. 'Composition' refers to the structure of the economy, that is, to the *output mix* that is produced, which varies according to the specialization of a country. Economic growth will be environmentally beneficial if it causes the economy to move toward less polluting outputs. 'Technique' refers to *how* a product is obtained, which includes both the input mix and the production process. Technological development associated with economic growth might help in substituting 'dirty' inputs and processes with cleaner ones. In terms of the neoclassical production model, a change in the input mix corresponds to a move along the isoquant while a more efficient process corresponds to a downward shift of the isoquant.

One can think of composition and technique as *channels* through which economic growth can eventually become beneficial to the environment. Which are then the *driving forces* that have been thought to operate through these three channels? To answer to this question it is interesting to read Panayotou (1993, p. 1) who affirms that "At higher levels of development, structural change towards information-intensive industries and services, coupled with increased environmental awareness, enforcement of environmental regulations, better technology and higher environmental expenditures, result in levelling off and gradual decline of environmental degradation."

This quotation summarizes the major ideas thought to predict an EKC curve, that is

1. economic growth brings along structural change ('composition' effect) and
2. technological development, which makes available a wider range of 'solutions' and lowers intervention costs. In terms of consumer theory this can be thought of as a decreasing price for environmental services.
3. Economic growth increasingly harms the capacity of the natural environment as resource provider and absorption sink, involving an increasing awareness of the environmental problems which is also fostered by
4. the advancement in knowledge, which improves our understanding of human impacts on the environment and their feedbacks on human welfare.
5. Finally it is often assumed that the environmental quality is a luxury good; that is, its income elasticity is greater than one and needs not be demanded at low levels of income.

Points (2) to (5) refers to the technique effect which is supposed to operate because economic growth brings both more potential for lowering the human impact on the environment (2) and more willingness to pay for environmental services (3), (4), and (5). Technique effect is then thought of as rooted in consumer theory predicting a more than proportional relationship between income and demand for environmental services. We can easily observe this with the help of Figure 2 that depicts a standard consumer choice problem. Suppose that preferences can be represented by a Cobb–Douglas utility function $U = CQ$, where C is a bundle of consumption products and Q is environmental quality. Q depends on what is freely provided by Nature (and affected by human activities), α, and by resources spent to improve environmental quality, E. For the sake of simplicity, suppose $Q = \alpha + E$. Figure 2 shows the problem of the consumer who has to allocate her/his income between E and C, having the utility function $U = C(\alpha + E)$ and facing a price for C equal to p_C and a price for E equal to p_E. The broken line containing points 'a,' 'b,' 'c,' 'd,' is the income–consumption curve that shows the optimal solutions when income changes. For low levels of income, the consumer is forced into corner solutions, e.g., point 'a,' where the demand of E is constrained to zero, while the optimal one would be negative, in 'a_0.' From 'b' onwards income becomes sufficient for the consumer to spend in E.

The effect of environmental degradation (3 above) is captured by decreases in α, which forces the consumer to spend more on E: the indifference-curve map changes so that the income-consumption line moves left (not shown), involving, e.g., point 'd_1' as an optimal choice. A similar change in the indifference-curve map can be thought of as caused by a better knowledge and awareness (4 above). Note that, due to the decrease of α, the utility in d_1 might be lower than the utility in 'c.'

The effect of technological improvement (2 above) can be thought of as lowering the price for the intervention on the environment, p_E, involving a steeper slope of the budget constraint, which in turn moves the income consumption line to the left (not shown) and makes it steeper (not

Figure 2 The increase in the demand for environmental quality.

shown). As a consequence, the demand for E becomes higher. Given the same level of income as in 'c,' the optimal choice with technological progress and environmental deterioration would be 'd_2.'

Following these lines of thought, the bell-shaped curve between environmental quality and per capita income is easily obtained. In the first stage of development, the willingness to give up consumption for getting better environmental quality is very low or absent. As long as income grows, the environment becomes increasingly deteriorated and willingness to pay increases. We become more aware of environmental problems while technology advancement makes environmental interventions less. Obviously, none of these conditions is necessary. What is needed is that willingness to pay for environmental services increases strongly enough to stimulate mechanisms able to offset the damages produced by the income growth via the 'scale' effect. Among those mechanisms one can include tighter regulation and incentives to 'green' investments, emergence of less environmentally damaging consumption and defensive expenditures. It is worth noting that other factors have been put forward in favor of the EKC hypothesis, such as economies of scale in the pollution control techniques (e.g., Andreoni and Levinson, 2001) or institutional arrangements (e.g., Panayotou, 1997). These factors allow more effective law enforcement and regulations, lower levels in subsidies hiding resource scarcity, higher probability of accepting environmental concerns, and better regimes of property rights. Concerning the latter point, some authors argue that a larger extent of private property in rich countries allows for more efficient allocation involving lower negative externalities and environmental degradation (e.g., Cropper and Griffiths, 1994).

Using a different combination of the mentioned ideas, a large number of theoretical models were used, including growth models attempting to accommodate the dynamic interactions between the environment and the economy. These theoretical models show how an inverted-U relationship between environmental degradation and income can emerge. It has, however, to be admitted that the question is an empirical one. Building a theoretical model, although exciting from an intellectual point of view, can eventually prove to be rather useless if its predictions depend on parameters that are inconsistent with empirical evidence. Since data on the parameters used in the models are often not available, most of the debate on the EKC has focused on an empirical estimate of the relation between per capita income and various environmental indicators, as will be discussed in the next section.

Empirical Analysis

The EKC was born as an empirical question and remained as such. Most of the studies are regression analyses of the empirical relationship between per capita income and various environmental indicators. Regression analysis is about looking for models that are able to predict a dependent variable with the behavior of other variables, which are exogenous and independent from each other. In this case, this would imply 'explaining' (predicting) environmental degradation with models that take into account all potentially relevant variables and relationships, including the possibility of having more than one dependent variable.

This, however, clashes with the very narrative of the EKC, since the debate started with the explicit purpose of challenging the view according to which economic growth brings along environmental deterioration. In other words, the purpose was to understand whether the net income effect becomes eventually beneficial to the environment. This is done by univariate regressions, with per capita income as the sole, independent variable, that is, by estimating a reduced-form model (Grossman and Krueger, 1995, p. 359) of a complicated web of determinants and relationships.

Such a research strategy has advantages and disadvantages. On the one hand it bypasses the issue of data availability when including many variables but on the other it introduces many potential problems concerning the econometrics, in particular due to omitting relevant variables and simultaneity problems, due to the feedback from environmental quality to income and more generally, to sustainability (Arrow et al., 1995). In any case, a more standard approach, e.g., including other explanatory variables, is not consistent with the question the debate aims to answer, net income effect on the environment.

The econometric studies of the EKC vary according to different aspects, namely,

1. indicators (and databases) used to proxy income and environment, particularly if they refer to different geographical levels (city, regions, country, world)
2. units included in the sample
3. shape of the relation tested (quadratic, cubic, nonparametric)
4. the use of variables other than income as regressors
5. econometric bad practices (or even 'mistakes').

The choice of income indicator is relevant when the units of analysis belong to countries with different currencies. Some studies have used GDP at market exchange rates, which, however, does not necessarily reflect what individuals can buy domestically with their income, especially in economies not particularly open. For this reason the most used indicator is income expressed in purchasing power parities.

Several distinctions can be made to classify environmental indicators. A major one, which is not always acknowledged in the EKC studies, is between 'pressure' and 'state' indicators, referring, respectively, to pressures exerted by society on the environment, e.g., emissions or resource use, and the quality of the environment, e.g., concentration of pollutants or resource stocks. This distinction is central to the indicator framework adopted by many agencies, the Pressure-State-Response framework and its evolutions. It was developed by OECD at the beginning of the 1990s. (For details see http://www.fao.org/ag/againfo/programmes/en/lead/toolbox/Refer/EnvIndi.htm or http://ia2dec.ew.eea.europa.eu/knowledge_base/Frameworks/doc101182/). One also has to consider the geographical, urban, country, or worldwide level. Especially in the early studies, evidence of an EKC emerges for local pollutants (water and air) and not for more global ones. This is in accordance with the progressive move out of the urban areas of pollutant productive activities (due to rent increases). It is also consistent with the idea that local impacts are more likely to get tackled, particularly if their abatement costs are low.

A very relevant source of differences is the sample type. Also due to lack of long time series, data used are usually panels of time series observations for different units (Cities, States, Countries). Including or excluding units (or changing the time span) greatly affects the results, concerning both the existence and estimated per capita income of the turning point (that is the p.c. income level after which environmental degradation decreases). Obviously it is very important to exclude outliers, that is, units with peculiarities such that the others cannot imitate their pattern.

Since the purpose was to look for an inverted-U relationship, some of the earliest studies tested for a quadratic relationship between environmental indicators and income. The cubic relationship became soon more popular since it allows for more possible shapes, depending on the estimated values of the parameters. To further avoid the problem of forcing data into a specific (time) frame, since the 2000s (Millimet et al., 2003) some EKC analyses used semi-parametric methods. With these methods the dependent variable is estimated as a smooth and continuous (possibly nonlinear) function of the regressor, allowing for freedom in the shape of the relationship.

Despite having introduced the EKC as a reduced form story, with income as the unique regressor, in most studies other regressors have been added basically to improve the fit of the estimates. Such a strategy (a kind of compromise between a structural form model and an univariate regression) gives results that are difficult to interpret. Once the significance and effect of some variables are isolated, what interpretation has to be given to the estimated coefficients of per capita income? For instance, a time trend is often found statistically significant and interpreted as a proxy for technological progress. Is it not growth in income that drives technological advancement and the other factors what ultimately make economic growth environmentally beneficial? Moreover, several explanatory variables are used without specifying either a simultaneous equation system from which the reduced form could be obtained or providing solid justifications involving the risk of ad-hocery.

Finally, some methodological and econometric bad practices have been pointed out. For instance, Luzzati and Orsini (2009) have emphasized that there are no reasons for using environmental pressure indicators in per capita terms, as is customary in the EKC literature. This is wholly inconsistent not only with using concentration indicators in absolute terms, but also with common sense. Actually it is not good news to observe pressure reductions in per capita terms if accompanied by a population growth that more than offsets pressure reductions. Nature does not care about per capita emissions. Total impacts are relevant. Theoretical models have acknowledged this (see, e.g., de Bruyn and Opschoor, 1997, p. 256; Aghion and Howitt, 1998, pp. 151–171; and the review by Brock and Taylor, 2005). The same is acknowledged by the EKC hypothesis, which is told as a story between total human pressure and per capita income.

Several authors raised econometric criticisms, particularly Stern (e.g., 2004). Early studies disregarded issues like heteroskedasticity, simultaneity, omitted variable bias, and time series properties. The latter is particularly relevant since nonstationarity variables easily give rise to spurious correlation. The unit roots test and the cointegration analysis, as commonly used in more recent works on EKC, prerequisite any serious EKC study.

Given the large differences in premises and methods, the expected outcome is a large variability of results of the empirical EKC studies. Actually a large spectrum of different patterns emerged, monotonic increasing and decreasing, inverted U-shaped, and N-shaped (Panayotou, 2003, pp. 62–67 contains a large summary table). Differences emerged also concerning the estimate of the turning point for the same environmental indicators, if there is one. Sometimes, actually, the turning point is only theoretical, since it lies outside the range of actual observations that is of an income level not experienced.

Hence the skepticism expressed by Copeland and Taylor (2004, p. 8) "about the existence of a simple and predictable relationship between pollution and per-capita income" is still valid.

An Assessment of the EKC Literature

The debate on the EKC has been highly controversial, acknowledging many caveats that have also brought forth favorable evidence. The paper by Arrow et al. (1995) in *Science* was perhaps the first critique to the emerging EKC literature. Since then, several scholars raised important issues, most of which are briefly reported above, that make overall the EKC hypothesis rather weak. Part of this weakness depends also on the EKC narrative being somehow naïve. There are several reasons for such a claim. For instance, the narrative contains the idea that poor societies do not harm the environment, an idea that is falsified by many examples of which the Easter Island is just one. Furthermore, treating the natural environment as a 'luxury' could be correct from the viewpoint of persons living in relatively rich societies. This might not be the case for people whose subsistence is secured outside the market in the natural environment (see Martinez Alier, 2002). Moreover, it is not obvious that relative increases in the service sector carry reductions in the material and energy throughput and in environmental impacts. For instance, air transportation is within the service sector. Consider also that weightless products such as software require both matter and energy for using them.

Even more importantly, it is somehow naïve to expect that the vague and complex concept of 'environmental degradation' can adequately be captured by a bunch of available indicators. Data availability is a major constraint in applied research. When data are available, it is because society is already conscious of those problems and could already have attempted to formulate some kind of policy response. Problems emerge and possible explanations are put forward collecting statistics to validate hypothetical explanations. For this reason, one should not be surprised to see that some available environmental indicators in some part of the world have improved over the course of time (and development). The question, however, is whether the adopted remedies have actually diminished the environmental impact or simply transformed into other (perhaps unknown) impacts. In other words, progresses on some environmental indicators could have been obtained at the expense of other environmental problems that have not yet attracted our attention. Hence, substitution/shifting of impacts could be more relevant than income growth for explaining progress in some environmental indicators.

Shifting is the basis of the 'new toxics' scenario which claim that as pollutants are cleaned up new ones emerge. Dasgupta et al. (2002, p. 148) attribute this hypothesis to the "pessimistic school" rather than considering it just as a hypothesis. I by the way do not find it fruitful to mix scientific reasoning and emotional concepts such as 'optimism' or 'pessimism.' Shifting is also relevant in explaining evidence of environmental improvement in many urban areas. Activities with high environmental impacts tend to move out of the densely populated areas. The same can be applied to international trade. As mentioned, the whole debate was born to assess the impact of trade liberalization between Mexico and the US. Many papers attempted to assess to which extent improvements in environmental indicators of rich countries can be attributed to migration of intensive pollution toward poorer countries, the so-called 'Displacement' or 'Pollution Haven' hypothesis. Since structural change in rich countries is not accompanied by equivalent change in the consumption structure, it is not surprising that some evidence in favor of the displacement idea has emerged (see e.g., Dinda, 2004). Part of structural change can be generically attributed to the low labor costs in poor countries associated with globalization. Migration of highly polluting industries can be attributed to weaker environmental regulations in poor countries, which in turn might put pressures on rich countries to mitigate the strength of their environmental standards ('race to the bottom hypothesis').

A few studies attempted to remedy the substitution issue by using indicators of overall impact, mainly material use (e.g., de Bruyn and Opschoor 1997; Eurostat 2002; Canas et al., 2003) and energy (e.g., Agras and Chapman, 1999; Suri and Chapman, 1998; Cole et al., 1997; Luzzati and Orsini, 2009). Energy is one factor "whose direct and indirect environmental significance is indisputable" (Jänicke et al., 1989, p. 25), the obvious reason being that our interferences with nature also arise from the power that energy gives us to move and extract matter. (For instance, by simply pushing a button, we are able to turn on engines that pump out water at unprecedented rates – rates which put water tables at serious risk of irreversible damage, no matter how clean the source of energy that we use.) Clearly, no 'best' indicator of complex phenomena such as environmental anthropogenic pressure can exist. Energy, however, is a rather good one due to its generic nature. When using energy in absolute terms, the EKC estimates do not support the EKC hypothesis at the world level, for panel data level (unless one is willing to include outliers), and for most countries (Luzzati and Orsini 2009, 2014).

A further step in this discussion is about impacts. Suppose that a genuine EKC emerges for environmental pressures, where genuine is supposed to mean total pressures and as depending on 'shifting,' that is on substituting one kind of pressure with another ones or moving the pressures to other regions. What can we predict about the state of the environment? An issue that has been acknowledged since the early stage of the debate is that of irreversibility. Even if pressures decrease, they might have already surpassed thresholds and have provoked irreversible changes in the environment with high costs to human society. 'Tunneling' the EKC was often called for, that is, implementing policies in order to shift down the EKC and avoid reaching too high levels of pressure.

The issue, however, becomes now to understand what 'too high' means. This would require not only to understand the complex relationship between pressures and the state of the environment, but also between the latter and the feedback on the economy and its impact on human well-being and sustainability. A precautionary approach might be a wise route to follow, particularly, if accompanied by the help of life sciences. If we did this we would discover that already in the 1930s a relationship was found between efficiency and size of animals, the so-called mouse-to-elephant or Kleiber's curve (e.g., Miller, 1986). This curve predicts that the higher the size, the greater the efficiency of animals. (An echo of this can be found in the economic debate over the Jevons' paradox (known also as rebound effect).) While waiting to see whether this also applies or not to efficiency induced by technological improvements, a precautionary approach would be for rich countries starting a diet to reduce their material obesity.

Abstract

Labeling theory emerged as the dominant perspective in the study of deviance in the 1960s, though its origins can be traced to Durkheim. Labeling theory, influenced by symbolic interactionism, dramatically transformed the field by redefining what constituted deviance and what was significant to understand about deviance. It dominated the study of deviance for a quarter of a century. While its zenith has passed, it remains, as an aspect of societal reaction theory, an enduring perspective that continues to generate research refining the perspective and extending it to new areas under related concepts such as stigma.

The study of deviance has been shaped by a variety of streams of influence over the years each pulling the field in different directions. The earliest roots of the study of deviance can be traced to Emile Durkheim's (1897) pioneering investigation of suicide, over a century ago, in which he established a relationship between the organization of society and rates of suicide. From the onset, a dominant stream of influence has been this 'positivistic' perspective where (1) 'deviance' referred to norm-violating behavior, such as crime, delinquency, suicide, alcoholism, etc., and (2) research was oriented toward identifying the social causes or etiology of the norm-violating behavior as well as its consequences upon the larger society.

In the 1960s, however, the traditional positivistic perspective was eclipsed by what has been characterized as the labeling, societal reaction, or the interactionist perspective. The roots of this perspective can be traced to a second line of investigation of Durkheim (1895) in *The Normal and the Pathological*, which shifted attention from how society generated nonconforming behavior to how and why society created criminals through societal reaction. Durkheim's primary focus in this work was on macroanalysis, establishing the functional paradigm, and applying the paradigm to the study of the (positive) contributions of crime/punishment in establishing and maintaining social order and cohesion in society.

However the societal reaction perspective did not gain traction until over half a century later in the 1960s, where it was redirected away from functionalism and macroanalysis toward microanalysis with a focus on social process rather than social structure. This shift in focus was largely the result of the very strong influence that both symbolic interactionism and the Chicago School had on the field of deviance and redirected the societal reaction perspective toward microanalysis and a focus on social interaction. The works of early pioneers such as Tannenbaum (1938), Lemert (1951, 1967), Becker (1963), Goffman (1961, 1963), and Scheff (1966) brought labeling theory front and center to a position of preeminence in the field. Labeling theory generated much interest, research, and excitement in the field and continued to dominate the study of deviance for almost the next quarter of a century. It gave rise to a variety of theories and research studies which redirected the traditional positivistic study of deviance toward new issues and concerns. Though its popularity began to wane by the 1980s, its legacy remains a vital perspective today in the study of deviance. Since the late 1990s there has been a resurgence of articles and books focusing on evaluating labeling theory, reinterpreting and refining the theory, and applying it to new areas of study. Labeling theory is thoroughly embedded in the fabric of deviance theory today. Several outstanding recent histories of labeling theory have documented the resurgence of deviance theory (Plummer, 2011; Matsueda, 2014).

There also is no all-encompassing labeling perspective. Because it developed in a piecemeal fashion, in a variety of areas, focusing on different issues, its relationship to the larger body of sociological theory, such as societal reaction theory or symbolic interactionism, has not been clearly explicated. In addition to its macro and micro focuses, it also assumed quite different forms as it was applied to different types of deviance and to different facets of the processes of deviance. It did not evolve into a coherent body of theory, incorporating both macro and micro concerns, integrating the disparate and seemingly unrelated studies.

One of the first attempts at integrating the disparate strands of many diverse studies which sought to bring them together in a more unified way was an iconic text by Earl Rubington and Martin Weinberg (1968) which described this emerging body of theory and research as the 'interactionist' perspective. It undertook efforts to incorporate both the more narrow micro concerns of labeling theory, focusing on the effects of labeling on the individual, while at the same time including research studies that were broader in scope than what might have been typically regarded as labeling theory. Studies of institutions of social control such as the court, police, prisons, and social work agencies as well as studies dealing with the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03161-5

emergence of subcultures and social movements began to dot the landscape. These studies, however, required a broader framework than what the term 'interactionist' perspective might convey. Therefore, a more encompassing conceptual framework is needed to contain the range of concerns in this array of theories and studies. However, the effect of symbolic interactionism on societal reaction theory was to keep the focus on the micro and social psychological aspects of the labeling process. Whereas Durkheim focused on the macro aspects of societal reaction in maintaining the social system as did later scholars Erikson (1966) and Moral Panic theorists (Nachman and Goode, 1994), who focused on the larger implications of societal definition and reaction. The more generic 'societal reaction' perspective, which subsumes both the narrower micro concerns of labeling theory as well as broader macro perspectives, will be employed as the primary framework in this analysis.

The rise or fall in popularity of various paradigms in the study of deviance often reflects their popularity in sociology generally. In both mainstream sociology as well as deviance theory, the popularity of various paradigms is influenced by the tenor of the times. Times of social unrest usually bring conflict theory into prominence, as it did in the late 1960s and 1970s, when cities were aflame and blood was running in the streets. Functional models of society often fade from favor as they do not reflect the circumstances of those times. Whereas during periods of relative calm and prosperity or increasing cultural diversity such as the late 1950s and 1960s, symbolic interactionism and images of negotiated social orders rise to prominence, as they mirror the social conditions of the times. Therefore, changing times often lead to changing paradigms within a discipline. These short-lived cycles, in deviance theory have been noted as 'generational effects' (Plummer, 2011) or paradigm shifts (Kuhn, 1970).

Symbolic interactionism left its substantial mark on labeling theory. In addition, the orientation of the labeling theory got continually refocused as it was applied to different forms of deviance, such as crime, delinquency, mental illness, drug use, gangs, sexual orientation, or disability. This fragmentation of labeling theory became so pronounced that some critics did not view it as a theory but only a loosely tied together body of propositions which acted more like a sensitizing perspective than a theory.

Nonetheless labeling theory dramatically shifted attention from the traditional positivistic concerns of viewing deviance as behavior which violated norms and seeking the social causes of rule-violating behavior. While employing the same term, *deviance*, they radically redefined both the term and the field of study. They asserted that what deviance fundamentally refers to is *actions* or *people* that elicit *social disapproval, condemnation, rejection, or exclusion*. Furthermore, they asserted sociologists can never deduce in advance what will be sanctioned by idealized versions of the norm. Norms were reconceptualized from 'objectively determinable' to 'subjectively problematic' (Rubington and Weinberg, 1968). Moral norms must be studied in action as they are created, invoked, or applied in everyday interaction, and that you can never tell what the norm is until people are actually negatively reacted to by others and this is highly variable (Becker, 1963). It is other's reaction to them that makes them deviant, not the act itself. Furthermore, people can elicit social condemnation without violating social norms, and such individuals are still to be regarded as deviant from this perspective. This is why *positive deviance or hidden deviance is* an oxymoron. It is not the act that the person engages in that makes them deviant. It is only the reactions of others that confer their deviant status upon them, no matter their actual behavior. Hence the meaning of the term deviant shifts from *behavior* in which the individual engages, in the positivist perspective, to their *status* in the group and how they are defined by others in the labeling perspective. That is determined by the reactions of other members in the group. Thus the concerns and research efforts of labeling theorists were then directed to *the social definitions and causes of labeling as well as the consequences of labeling especially on the individuals' subsequent behavior, self, identity, and possible career of deviance*. Though the variable nature of applying rules and labels to individuals was commonly investigated, the variable responses to the labeling by prospective deviants, was less well examined, with few exceptions (Goffman, 1963).

Labeling theory also shifted attention from the harmful effects of deviance on society, frequently presumed by positivists, to the harmful effects and consequences of official control and labeling on the lives of individuals who are designated deviants by society. In addition, the emergence of labeling theory served to raise questions about value positions which are implicit in particular ways of conceptualizing and studying deviance (Mills, 1943) by incorporating the perspectives of deviants, as Becker's (1964) title, *The Other Side*, aptly conveys. It gave a type of legitimacy or validity to the perspective of deviants. Including the perspectives of deviants also bears the mark of the Chicago School's emphasis on obtaining rich ethnographies on the lives of deviants giving them a seat at the table in the dialogue. There are even current pleas (Fitch, 2010) urging reconnecting labeling theory to its early roots to Dewey by reemphasizing that isolating, stigmatizing, and condemning individuals creates an underclass contrary to democratic ideals. The morality of labeling cuts both ways. Other aspects of labeling theory also reflect the strong influence of symbolic interactionism, particularly theorists such as Mead (1934), as they shaped a view of social life as fluid, reality as socially constructed, meaning and order as negotiated, and took a less deterministic nature of social interaction with a focus on social process rather than on social structure in place of the stricter determinism characteristic of functional/positivistic approaches.

Societal Reaction Perspective and Labeling Theory

Central to sociological analysis is 'part to whole analysis' and in this vein it would be helpful to place labeling theory in a larger contextual perspective. It is asserted that labeling theory cannot be fully appreciated apart from its connection to societal reaction theory and that it can be viewed as a subbranch of societal reaction theory, which includes micro, meso, and macro levels of analysis. Furthermore, the various levels of the perspective are intimately intertwined. Societal reaction theory can be viewed as comprising three streams of interrelated studies and theories: (1) microanalysis encompassing studies dealing with the traditional concerns of labeling theory, (2) mesoanalysis exemplified by studies dealing with larger focuses and

structures such as agencies of social control, professions, social movements, etc., and (3) macroanalysis dealing with the interconnections of labeling processes to the larger social structure and social system, perhaps even extending to the world order and global processes related to patterns of social control.

1. Labeling theory would fall into a more narrow focus on the micro aspects of societal reaction theory such as consequences of labeling on the individual, their self-concept, identity, life chances, and subsequent deviant actions and entrenchment into deviant careers.

Tannenbaum (1938) was among the first to redefine the concept of deviant and redirect study to the effects of labeling and how it creates what Lemert (1967) calls 'secondary' deviance; deviance that is a product of the labeling process itself. Whereas positivists had focused their attention on the initial rule-breaking act or primary deviance. The labeling apparatus could be viewed as a system of amplification of deviance, which paralleled concerns of mainstream sociologists with the process of socialization, more aptly described as resocialization. Becker's (1963, 1964) focus was more on the creation and application of the rules by moral entrepreneurs and enforcers, the various contingencies involved in labeling, and the importance of social definitions. The labeling approach led to a reconceptualization of norms as 'objectively determinable' to 'subjectively problematic' (Rubington and Weinberg's, 1968). Becker (1963), in his study of marijuana use and Scheff (1966, 1984,1999) in his analysis of mental illness, both highlighted the importance of learning the deviant role, which further targeted the amplification process of elaborating and stabilizing deviance. Reflecting similar concerns, Goffman in *Asylums* (1961) elucidated the systematic efforts of institutions of social control to transform individuals' identities into deviant ones, in order to more effectively manage them in a bureaucratic system. This work addressed social control institutions and more encompassing institutions he described as 'total' institutions. His *Stigma* (1963) called attention to the central place of stigma and the critical role that social acceptance plays in the study of deviance, not only in the lives of deviants but in the underlying threat of embarrassment and loss of face that everyone faces at every moment in everyday interaction. All individuals share with deviants, though in a lesser degree, the experience of managing stigma. When social rejection becomes more extreme and spills over into other roles and situations, it reflects the terrain of deviance. Normals can usually shed the devaluation at the termination of the interaction sequence as it does not usually follow them into new situations as it may among deviants. Thus the 'meaning' as a deviant the person comes to have for others is constructed through social interaction by the treatment the individual receives, which is critical to creating deviants. The meaning is revealed in the process of social interaction where the individual is constructed out of the actions and reactions of others.

This tradition was often characteristic of subsequent research in criminology where a plethora of studies emerged with their focus on the consequences of formal systems of social control on recidivism. Here the findings show somewhat consistent effects of labeling and the formal processing of criminals on subsequent law-breaking behavior and reincarceration. Some studies, however, showed more inconsistent effects and suggested reformulation of the theory by specifying the conditions under which labeling is likely to be effective, in order to more adequately test labeling theory (Paternoster and Iovanni, 1989).

More recent studies extend the theory to new areas such as gambling, victim perceptions, and drug use. In addition, they explore differences in formal and informal labeling, the varied conditions under which labeling takes place, the type of sanctions imposed, age at which labeling occurs, the duration of the effects of labeling, areas impacted by labeling, as well as differences in the effectiveness of labeling on various groups differing in gender, age, ethnicity, etc. The studies showed significant differences and point to the necessity of further research characterized by more refined formulations more adequate controls over these variables. Efforts were undertaken to identify how the effects of labeling are mediated, whether through (1) identity change or (2) cumulative structural disadvantage through the exclusionary process of labeling. Both contribute to explaining the variance. More specification is needed of the types of deviance, sanctions, and conditions under which labeling takes place, so a more precise understanding of how the process of labeling influences outcomes. The introduction of more sophisticated techniques such as modeling theory has increased the explanatory power of labeling theory in delinquency (Hayes, 1997). The research and the concerns raised by labeling theory, despite the lack of highly controlled studies, has led to an increased use of alternatives to traditional methods of social control in society such as drug courts, home monitoring, alternatives to incarceration, and techniques of radical nonintervention (Schur, 1973).

This pattern of research was also characteristic of studies in the area of mental illness where research explored the consequences of labeling on symptom remission, rehospitalization, and the stigma the individual experienced, though more inconsistent effects were found with respect to symptom remission and rehospitalization (Scheff, 1967, 1999; Gove, 1980; Link et al., 2001). Alternatives to hospitalization such as deinstitutionalization were undertaken on a mass scale in states like California, though these programs failed to provide help for the individuals in the community which ultimately led to an increase of the mentally ill among the homeless and now prisons and jails have become the largest mental hospitals in the nation. Self-help and twelve-step programs have arisen around an enormous range of 'addictions' reflecting some deprofessionalization of the management of deviance countering somewhat the trends toward the medicalization of deviance. Studies in the area of mental illness also urge a more thoughtful reformulation of the theory in order that more precise predictions can be made.

The most recent direction that labeling theory and microanalysis has taken, spearheaded by the work of Link et al. (1989, 2001), has been under the terms of stigma and stigmatization. Stigma studies tend to show consistent negative effects of labeling and have been linked to self-esteem, earning power, ties in the community, psychological symptoms, and satisfaction with life (Markowitz, 1998).

Plummer (2011) noted that while many current researchers do not explicitly identify with the labeling perspective or locate the relevance of their findings to the tradition, their findings fall

squarely in labeling theory paradigm. Ordinary sorrow is transformed into depressive disorder that illustrates medicalization of deviance as life history criminology, which relates subsequent criminality to involvement in the criminal justice system is old wine in new bottles. Also one cannot ignore the impact of labeling theory on other disciplines such as psychology, psychiatry, social work, special education, etc. (Corrigan, 2004). Numerous studies raise serious questions about the nosology and types of mental illness of the field of psychiatry, based on the Diagnostic Statistical Manual, calling into question not only its reliability but also its validity. The goodness of fit between these fundamental diagnostic categories and the symptoms manifested by individuals is very poor, lending credence to Scheff's claims and affirming social constructionist's interpretations of the term 'mental illness.'

All the above studies and efforts fall into this more narrow focus on societal reaction traditionally associated with labeling theory.

2. Mesoanalysis attempts to link labeling perspectives with larger structures in society such as agencies of social control, social movements, and the emergence of subcultures or professions.

More encompassing studies on labeling processes and societal reaction take into account the creation of social types, the consequences of large formal agencies of social control (Goffman, 1961) such as courts, police, prisons and apply these perspectives to other bureaucratic systems such as school systems and the tracking of students or social work agencies. These studies investigate social processes and systems with a much broader scope than just focusing on the effects of labeling. Studies in cultural criminology, public reactions to crime, and the role of media in shaping public responses to crime also reflect mesolevel concerns of societal reaction theory. Developing an understanding of how these institutions operate as social systems, such as the "Theory of Office" (Rubington and Weinberg, 1968), as well as their role in the larger society in managing deviance also demonstrates linkages to larger structures in society sometimes edging the labeling perspective toward macroanalysis.

In mesoanalysis, this social 'meaning' key to the term deviant is made more structural by introducing the concept of *status* as defining the deviant, and along with the concept of 'master status,' deviant status is placed in a larger structural context of analysis or in Goffman's terms a larger frame. Taking it further, deviance can be seen as a form of social stratification based on 'status groups' in Weber's terms referring to the prestige, respect, or dignity of the person so as to make social acceptance possible through status claims. Celebrities would form the highest tier, ordinary people an intermediate tier, and deviants fall at the bottom of the hierarchical system. Therefore deviance can be studied within a structure of stratification and inequality of prestige or social acceptance in the same way other systems of inequality are examined in mainstream sociology.

Mesolevel research also examines the effects of labeling systems on both the deviants and on other institutions in society. This tradition of social constructionism has embodied the study of whole professions such as psychiatry, medicine, and the pharmaceutical industry and their roles in medicalizing deviance. Some of the richest studies on professions have emerged from studies in the field of deviance. These studies integrate 'structural' aspects of large-scale organizations and institutions with micro level interpersonal and individual effects of managing deviance.

3. Macro concerns in societal reaction theory had its roots in Durkheim (1895), and reemerged in the 1960s with the resurgence of labeling theory. Aspects of macroanalysis can be found in Erikson (1966), Scheff (1966, 1984, 1999) where the larger functions of labeling deviance or mental illness were examined, and in Moral Panic analyses (Nachman and Goode, 1994) which focused on larger societal reactions. Studies that examined aspects of deviance as precursors to social movements such as gay pride or the discrimination associated with mental illness, like the emergence of these movements were efforts to cope with deviant status in society. These studies and theories embodied macro perspectives.

Labeling concerns are also linked to macroanalysis by including the society's system of social types in their analyses. The boxes or categories within which individuals are placed are larger societal constructions. Furthermore, Scheff's (1966, 1999) analysis of mental illness as a 'residual' category (placing all forms of deviance that do not fit other established types or categories), permits the larger structural system's integrity by coping with the range of unacceptable behavior that does not neatly fit into the conventional system of social types, and ties his analysis to macro concerns of system maintenance. Furthermore, Scheff's (1966, 1999) assertion that the function of labeling is to (1) protect the status quo and (2) preserve the underlying social reality, also speaks to the issues raised by Durkheim in his macroanalysis of deviance. Less well explored, but equally critical to a larger macroanalysis, are Scheff's and Goffman's notion of psychiatric symptoms reflecting the *taken-for-granted residual rules of society*. They are a reflective prism on the assumptive world of that social system. Thus psychiatry becomes a way of policing a certain part of the moral terrain. This extends Durkheim's macroanalysis of crime to mental illness. For Durkheim creating criminals is a way to define moral boundaries and similarly for Scheff, labeling people as mentally ill is a way also to define moral boundaries of the taken-for-granted world.

Another stream of influence flowing from societal reaction perspectives arose as the similarity between the plight of deviants and other oppressed or stigmatized groups came to be recognized in social movement theory. The connecting of gay rights, the disability community, prisoner rights movements, etc. were seen as instances of civil rights struggles and the larger issues of equality and civil rights came to the forefront forging an alliance between larger concerns of social acceptance and the power of the state. Increasing convergences between issues studied by deviant theorists and those in mainstream sociology can be observed. The plight of deviants and threats to their civil rights arose along with other stigmatized and oppressed minorities became an increasingly important issue in recent times. This was foreshadowed by Durkheim's analysis of the growing importance of the individual and individual rights in modern society as the sphere of the collective morality diminished

with industrialization. Parsons pushed the analysis of modernity further and viewed increasing democratization as a consequence of modern society. Thus these movements may reflect a larger transformation to attain dignity and rights for all in society even among the lowest of the low, social outcasts.

Within this macro tradition are also studies demonstrating relationships between labeling systems and macro structures. For example, there has been research linking increasing rates of incarceration to the creation of prisons as the new Jim Crow system. Some view increased incarceration as a result of the later stages of declining empires linking labeling processes to the larger world order. Thus labeling may be driven by much larger macro concerns than deviance theorists have yet explored. Conflict/radical theorists have sought to link increasing incarceration to the late stages of capitalism as a way of coping with the bourgeoning unemployment. Studies investigating the current decriminalizing of marijuana bear directly upon Durkheim's hypothesis that societies seek to maintain 'optimum' amounts of crime through efforts at loosening boundaries when there are excessive numbers of deviants, as was the case before the repeal of prohibition in the U.S. Current mass releases of inmates from prison also reflect society's efforts to balance the creation of criminals with social resources. In addition, investigations of efforts by society to create new categories of deviants such as terrorists and extending that label to eco-terrorism or animal rights terrorism links labeling processes to efforts of state or corporate control to employ labeling as a means of extending their power and control in society. Thus issues of societal reaction fit neatly into aspects of conflict/radical perspectives of deviance as well and merge easily into macroanalysis.

Falling squarely in the macro tradition were investigations and studies which explored variations in labeling processes by type of society (Pfohl, 1981; Raybeck, 1988) which focused specifically on macro–micro relationships between narrower concerns of labeling and social control at the micro level and broader issues of social organization societal reaction, with an emphasis on macro–micro integration.

These trends in research and theory illustrate the various strands of labeling and societal reaction theory and the range of societal reaction theory. Overall the trends in research over the last half century has been moving toward expanding the range of societal reaction theory, identifying convergences in different areas of deviance, and proposing refinements in the theory by specifying the relevant variables and types of controls necessary to isolate the effects of various systems of labeling. There are calls for efforts to integrate the various strands of societal reaction theory into a more encompassing and coherent perspective and designed research to examine the overall system of social control.

Not only may it be impossible to separate aspects of labeling theory as issues seem to be strongly interrelated. It would be artificial to separate them as independent lines of inquiry without seeing their interconnection. It may be true that separating deviance theory from general sociological theory may prove increasingly unfruitful since the problem of deviance (disorder) is the opposite side of the coin of the 'problem of order' which has been a foundational concern since the inception of the discipline. A coherent sociology will attempt to unify instead of fragment the field into subdisciplines. Separating rather than integrating disciplines may result in fracturing our grasp of the world. Each science is a strategy of abstracting from a complex world. Otherwise everything would have to be said at once to capture the immense complexity of the world. On the other hand, by separating disciplines, we lose the interconnectedness of nature.

If labeling theory is to advance today, it must consolidate a variety of disparate concerns into a more coherent overall theory. Currently it sensitizes researchers to specific issues in the study of deviance without integrating its various facets showing the relationships among the diverse concerns on both a macro and micro level that have been embraced by labeling theorists in order to move from a perspective to a theory.

Deviance theory has not developed as a cumulative endeavor where each research study builds upon previous studies and theories are modified on the basis of empirical findings, so there is a close correspondence between the state of research and theory. If the field is to advance significantly the various strands of labeling theory, positivism, and conflict theory have to be pulled together within the various subareas, and then in turn has to be integrated into mainstream sociological theory.

Labor, Division of

Wolfgang Littek, University of Bremen, Bremen, Germany

Abstract

Labor (or work) denotes an activity necessary to secure human existence. Division of labor refers to the separation of tasks and the specialized allocation to different workers. It is an active force in social structuring, economic development, and the everyday experience of individuals. Whereas changes within premodern societies have been slight, the rise of capitalist industrialization has caused a tremendous expansion of the detailed division of labor in large-scale manufacturing accompanied by a complex social division of labor in society. Various forms as well as the dynamics of structural change of the division of labor are discussed. An overview of main theories concludes the article.

Division of labor, which refers to the system of differentiation and specialization of work tasks, is a feature of social structuring found in all human societies. In its forms it varies widely and changes over time. The division of labor creates interdependencies between the single specialized actors. Families, enterprises, and organizations, as well as national economies and international trade relations, are seen as structures of division of labor. Whereas simple societies show very little differentiation into specialized tasks or occupations, some highly developed societies of today discern among more than 40 000 different occupations, with additional specializations on top. It is helpful to distinguish between a narrow, technical-economic understanding and a broader, social understanding of 'division of labor.'

The article will briefly consider the complexity of the concept by looking at different levels and forms of the division of labor and at its role in the development of human history. The main attention will be given to the division of labor in modern industrial-capitalist societies. It will become clear that the division of labor underlies a permanently ongoing structural change, which implies that by no means may it be considered a static concept.

Labor

Labor or work refers to the execution of tasks that serve a useful purpose both to those performing them and to society at large to secure their existence and preserve the environment. Only humans perform work in the sense of using creativity, conceptual, and analytical thinking together with manual abilities to transform nature or to be of use to society. A distinction generally is made between work and labor. Work is connected more with positive aspects. In conjunction with creativity and interaction, it is seen as being a human need and as forming a basis for self-respect. The word 'labor' is derived from the Latin (laboris) and implies toil and distress. Hence, labor alludes to arduous work, done under some duress, and often under control of others (Standing, 1999; *see* Work, Sociology of). But the differential use of these terms is in fact not that strict. With regard to the specialization of tasks, however, it is common to speak of 'division of labor,' and not of 'division of work.'

Divisions of Labor: Concepts, Levels, and Forms

The fact that no society exists without at least some division of labor does not imply that this is caused by natural differences (such as biological differences between women and men, by race or age, or by differing personal aptitudes, for example). Any existent division of labor is always human-made and its forms are socially shaped. Throughout human history the division of labor has grown increasingly diversified, but only rather recently has it reached the complexity we are familiar with due to the growth of production and trade, the industrialization process, and the development of modern societies with all their specific institutions.

Concepts

It is necessary to recognize that for 'division of labor,' two different concepts are in use:

1. In a narrow sense, the concept is used in an economic or technological context and describes the breakdown of a complex productive task into a number of detailed and simpler tasks. This is known also as 'detailed' or 'technical division of labor.' The most renowned example in social sciences is that of Adam Smith (1776) for pin needle production. By splitting up the traditional holistic pin production by one craftsman into particular subtasks for different workers, such as cutting the wire, making the head, the body, packaging, etc., a sharp increase in output was reached. This sharp increase in productivity was the ultimate reason for the separation and specialization of tasks. It marks the introduction of modern manufacturing and led to the development of large industries.
2. Much broader is its use in a social context meaning because the labor performed by a person reflects his or her social standing in a group or in society. Recognized here is the connection of the division of labor with social differentiation. On the societal level, everyone is affected by the great differences in social esteem, economic power, and the distribution of wealth due to his or her standing in the existing division of labor. Any achieved social division of labor represents a result of the 'struggle for survival' in which individuals are unevenly successful (*see* Inequality, Social; Differentiation: Social). This social concept includes the forces of social cohesion or disintegration in connection with

the division of labor, or the importance played by solidarity and morale in a society (this aspect was first, and powerfully, developed by Emile Durkheim (1893/English 1984).

In a schematic form, the two concepts may be summarized thus:

Detailed division of labor	*Social division of labor*
Division in connection with *economic or technological reasons* (Based on society-specific institutions for work; resulting in separated subtasks, dependency, necessity of coordination)	*Division existing along social criteria* (Based on gender, power, skills, cultural laws, etc.; resulting in social differentiation, social inequality, necessity of social integration)

Levels

Clearly, 'division of labor' is a complex term and also may refer to different levels of human activity. The division can extend from the household or family work on the microlevel, through work organizations on an intermediate (meso-)level, to divisions in society at large on the macrolevel, and finally to the entire world on the global level. Examples of divisions of labor on the various levels are the domestic division of labor; the organizational division of labor in and between workshops, enterprises, or administrations; the occupational or regional division of labor in a country; the division of labor in production networks stretching nowadays often across national boundaries; and finally, the international division of labor, where economic globalization is affecting workers in the developing as well as the developed world.

In schematic form, the levels may be differentiated as in this overview:

Levels of the division of labor			
Microlevel	*Mesolevel*	*Macrolevel*	*Globallevel*
For example, domestic or familial division of labor	For example, division of labor in organizations, enterprises, administrations (or between them)	For example, occupational, regional, product-related, or national division of labor	For example, international division of labor, international trade

Forms

Furthermore, different forms, or types, of division of labor are to be recognized. Certainly, to the oldest forms belongs the sexual or gendered division of labor, that is, the division of tasks between women and men. This reaches far beyond the household and the family. It is clearly of importance in the area of work but is recognizable as well in social, political, cultural, and religious functions. Even in most modern societies, more or less discrimination exists by which women do not have equal access to functions in these fields (*see* Gender, Economics of).

Other forms of division may be based on age, ethnicity, heritage, or skills. Or they may be due to the size of workshops, to regional expansion of markets, to national characteristics, or to rules in international trade and diversification. The importance of specific forms has changed very much in the history of human societies, and many forms have newly developed.

Here is a schematic overview of the (more important) forms of the division of labor:

	Forms of the division of labor
Division of labor by	Sex (or gender) Age Ethnicity Occupation Skill Hierarchy Heredity Specialization and organization in the workshop or enterprise Space or region Vertical or horizontal specialization within a society International trade

The Need for Coordination and Cooperation

Specializations and subdivisions in work tasks, however, create the necessity to 'unify' the fragmented and specialized subtasks again in order to achieve an integral result. Any fragmented subtask alone in a division of labor makes no sense for the larger social context. The more the tasks have been fragmented, the more they become dependent on coordination and cooperation. This 'unification' is reached differently at the different levels or at the various forms of the division of labor.

In the domestic division of labor, this 'unification' is reached by reciprocity within the family. With the upcoming of a number of specialized occupations in earlier societies, coordination was achieved by exchange of the various products. As a medium for this exchange, markets developed. They again gained enormously in importance with the invention of money as a generalized exchange medium.

Differently achieved is the coordination of divided subtasks in large-scale manufacturing, namely by entrepreneurial planning, which is based on domination and hierarchy. Between the various enterprises (and most other actors) in an economy, coordination is achieved again by free markets. (Only in the case of former socialist countries, the coordination was done by national planning.) In the international division of labor, the unifying process is achieved by foreign trade (which itself may be based either on free exchange or on coercion, as in colonialism).

In sum, the examples show that, basically, there exist two principles to gain a 'unification' for the subdivisions into partial work tasks: these are either the 'market' (with free choice) or 'planning' (based on domination or coercion).

Division of Labor and Socioeconomic Development

Viewing the long sweep of human history, the contrast between very simple and vastly extended complex social structures springs to mind. The extent of social differentiation is closely connected to the extent of the division of labor. Both accompany the shifts toward more complex societies.

Very little change occurred during the longest period in the history of humanity, which began almost 250 000 years ago with foraging as the means to secure survival. Most likely only some division of labor by sex and age existed. The agricultural revolution (between 8000 and 5000 BC) brought about a first important change. Humans transitioned from a nomadic to a settled lifestyle as farmers. A division of labor was prompted to store and provide food between growing seasons. This led to the rise of a leisured upper class and the creation of the first cities as places for exchange. The production of a surplus beyond self-provisioning then gave room to the emergence of specialized, artistic occupations (*see* Societies, Types of). Based on specialization and the concentration of power and artisanal aptitudes, the first 'high cultures' with some extension in the division of labor developed in some parts of the world, e.g., Mesopotamia, Egypt, later China, Middle and South America.

In addition, for a long time a large part of the world comprises societies characterized by rather little division of labor, as the overwhelming portion of productive tasks are performed as self-provisioning by farming. The family in these societies is also the productive unit for survival. With some development in agrarian cities, only a small part of the population is engaged in specialized occupations such as crafts, trading, religion, or warrior functions. Tradition is of eminent importance, and rarely are there any changes in the overall division of labor over long periods of time.

However, no linear progression occurred in human history toward ever greater complexity, no continuous evolution from simple to modern societies. Not infrequently, the division of labor was based on coercion and power. Unfree labor, as in slavery, was widespread in order to pursue labor tasks. Slavery, a system under which people are treated as property to be bought and sold and are forced to work, is still in existence in some parts of the world and was eradicated only in the late nineteenth century in several countries, including the United States (*see* Slavery as Social Institution). Feudalism in Europe and Japan during the Middle Ages was another system with division of labor based on coercion and power. Such societies were characterized by a generally accepted cultural legitimation for existent inequalities. The distribution of functions in the labor process in these societies is based on 'ascription' (being born into one's role and status), not on personal 'achievement.'

In sum, relatively static forces were dominant in the division of labor for thousands of years in human history. This came to an abrupt end when capitalism and industrialization in Europe began to transform the world (beginning in England in the early eighteenth century) (*see* Capitalism: Global; Industrialization). The last 300 years alone have seen by far more changes in the division of labor than all previous ages. Compared with the development up to that time, industrial-capitalist transformation marks a quantum leap for the division of labor. It rightly was labeled '*The Great Transformation*' in a famous book by Karl Polanyi (1944[2001]).

The Division of Labor in Modern Societies

The Institutional Frame

The capitalist-industrial mode of production was established on the basis of a number of institutions that previously did not exist. Along with the Enlightenment, a civil society was forming, empowered not least by the American and the French revolutions. The idea of a free and responsible individual spread. As a result, the notion that one person could be the owner of the labor power of another person (as in slavery) lost its legitimacy. Labor became now executed as free labor, at the disposition of the individual himself/herself. Labor now turned into a commodity: labor power is traded on labor markets, and the resulting division of labor is based on free will. This is so common to us nowadays in societies functioning under capitalist principles that it might seem to be natural to many people. But it is only a very recent invention of mankind.

Of course, not all work, not all division of labor, underlies capitalist principles even in today's modern societies. For the working person, the social relations and the social orientations in which the tasks are embedded are important. Aside from wage labor in the private sector of the economy, domestic labor and communal labor play a significant role as well. And, people in fact do work for a whole range of rewards and incentives, not only measured by money (Pahl, 1988).

However, it were capitalist principles and state regulation that caused the significant change from self-provisioning or artisanal labor to modern industrial and postindustrial working conditions. The major specific conditions relevant for the division of labor in capitalism and modern civil society, therefore, will be outlined below in short to help understand their uniqueness. (Socioeconomic literature here is abundant. Most is based, more or less, on the first grand analysts Marx (1867/English 1976) or Weber (1922/English 1968); *see* Capitalism: Global).

Separation of Household and Workplace

With the introduction of manufacturing in special premises, the domestic labor and gainful employment become separated. A previously unknown division is introduced between the public sphere of work and the private sphere of home. The function of the family (or the household) changes dramatically, as it is no longer a combined unit of production and reproduction. The division implies the separation between unpaid labor in the household and paid labor in the public workplace. This is responsible for a thorough change in the sexual division of labor, as it provides a new basis for power relations in the family and for the gender typing in employment outside. From the beginning, women are either excluded from paid work or only obtain access to less paid, less demanding jobs, but rarely to leading functions.

Concentration of Labor in Manufacture and the Factory

The assembling of great numbers of workers in one place, under single supervision, is the prerequisite to splitting up complex craft work, executed by one expert, into a multitude of detailed tasks performed by various persons. With this detailed division of labor, enormous gains in productivity are possible. This usage of labor carries a number of (economic) advantages: unskilled workers, who receive relatively low wages and are easily replaceable, can be engaged; the specific skill developed by a person in the specific subtask tends to get higher than that of a person performing the complete series of tasks; and finally, control over speed and output is easy. Fragmentation into simple repetitive functions is also the basis for the subsequent mechanization and automation, which again drives productivity.

With the introduction of capitalist manufacture, the 'separation of conception from execution' found its crystallization. However, some part of the productivity gains always are taken up by the efforts necessary for coordination, organization, supervising, and control of the partial tasks (i.e. management). Plus, a serious price has to be paid for rising productivity in this type of division of labor – namely, alienation and loss of motivation on the side of the workers in such repetitive jobs with little space for proudness and self-esteem as a 'producer' (*see* Alienation, Sociology of).

Private Property

In the process of industrialization, property acquires a new social function and is important for the division of labor in two respects. First, it provides for the owners and for those who are engaged in planning and controlling the legitimacy to enforce the detailed division of labor. Second, it provides the basis for the accumulation of wealth. Profit becomes the main motive for organizing a labor process, which was not necessarily the case in traditional societies. Capitalists ultimately only have the 'exchange value' in mind, whereas provision of a product or a service useful for the consumer ('use value,' in the terminology of Karl Marx) no longer is the main impetus for any production process. This implies that the social function and the importance of money change completely: from a generalized exchange medium on local markets to an abstract carrier of value and power that makes the world go round (*see* Money, Sociology of).

Free Labor

A labor market, where labor can be sold and bought as a commodity, was not common in human history. Quite frequently, societies in earlier times depended on the use of unfree labor (in slavery, serfdom, subjugation to a ruler). Those are the typical characteristics of a 'forced division of labor' into which persons often also got by birth. Modern development relies on formally free labor, which is free for contracting with an employer. The workers sell their labor power. This implies that social relations of a double character become relevant for wage labor: on the labor market, the relation is formally one between equals, whereas inside the workshop, the relation is one of subjugation under domination and power (Rueschemeyer, 1986; *see* Labor Supply).

Liberalization of Markets and Competition

The importance of liberalism for greatly increasing the wealth-creating capacity of a nation was strongly emphasized by classical 'political economics' during the Enlightenment of the eighteenth century. Unrestrained by administrative rules of government, a 'free market' would encourage producers to specialize in activities where they have a relative or absolute productive advantage. This implies pleading for political activity that aims at a specific design of national and international division of labor. Similarly, 'free trade' is seen to be to the benefit of all countries participating because of the advantages of comparative costs (main authors: David Ricardo, Adam Smith). Through specialization, producers benefit from greater dexterity, more efficient use of materials, time, expertise, and technology. At the same time, the invisible hand of competition penalizes ineffective producers by removing them from the market. This thinking is still powerful nowadays with the dominance of neoclassical economics almost worldwide, even though critics have widely pointed at the unrealistic assumptions inherent in the picture of the 'free' market.

Application of Science, Technological Change, and Automation

In the pursuit of profit and under the constant pressure of competition, science is systematically and permanently applied for the creation of ever more sophisticated machines and procedures to render production processes more efficient or develop new products. In contrast to traditional craft work, technological change now becomes a permanent feature of working life. Human labor that remains in the work process is forced to fill the gaps left by machinery, new technologies, and organization, and to adapt constantly to changing requirements.

Division of Labor and the Dynamics of Change

Change has remained a fundamental feature of the division of labor ever since industrialization altered occupational structures and skill requirements in an unprecedented manner. Today, ongoing changes in the division of labor on all levels, and in all dimensions, are mainly due to three megatrends (Graßl, 2000), which shortly will be dealt with: (1) the change from industrial society to service and information society, (2) changes in the gendered division of labor, and (3) globalization and international division of labor.

Change to Postindustrial Information Societies

In the last decades, highly developed societies have been leaving behind industrial production as the major field for employment. The 'service society' and the 'informational economy' have taken the ground, described, e.g., as '*The Rise of the Network Society*' (Castells, 2000). With information technologies, the occupational, regional, and international division of labor has expanded into new fields. Provision of knowledge-driven services, evaluations, information, guidance, analysis, finance, even caretaking, etc., now outnumbers industrial production work by far.

Increases in the professional level of many jobs and the professions as such gain in importance in highly developed countries. Lowly skilled, tightly prescribed work decreases in importance, and simple labor is often either relocated to less developed countries or eliminated altogether through automation.

Changes in Work Organization

Assembling people in large numbers and assigning them detailed tasks requires organizational planning to reach the common goal. As a result, organizations have become an indispensable feature of modern life in many areas, and 'organization theory' and 'management' have developed into indispensable fields of their own over the last century (*see* Organizations, Sociology of).

At the outset of industrialization, early enterprises were organized very much by patriarchic ruling principles or by the example set by the military. With the rise of capitalism, rationality and market principles grew vastly in importance. Aside from analyzing the emergence of legal rationality with the modern state, Max Weber in his '*Economy and Society*' (1922/

English 1968) worked out, more generally, the importance of rational behavior as a basis for modern administration and organizations and for modern work life in general.

Regarding production work, '*The Principles of Scientific Management*' by Frederick Taylor (first 1911, numerous reprints) then became highly influential for the improvement of industrial efficiency. At the core of Taylor's principles is the strict separation of conception (or planning work) from execution. Taylor advocated a division of labor that relies on tight control and hierarchy. All decision making about the 'one best way' of how to perform a task rests solely with management, thus destroying skills and use of their discretion on the side of the workers. Taylor's whole system based the division of labor on a low level of trust.

The industrialist Henry Ford added the disciplining power of the assembly line to the work process. Furthermore, he combined mass production with the cultivation of mass markets. Since then, bureaucratic organization, Taylorism, and Fordism have been so successful that they shaped the form of the division of labor and working conditions in industries all over the world, even in the (former) communist or state-socialist countries. (The latter, however, did not just seize the unique opportunity to realize a form of division of labor based on different, social principles, e.g., Sayer and Walker, 1992.) Many social scientists agree that the widespread application of Taylorist and Fordist principles of work reorganization led to '*The Degradation of Work in the Twentieth Century*' (as analyzed in a seminal study by Harry Braverman, 1974). The ongoing impact on working conditions in various countries is being discussed more fully, e.g., in the ensuing 'labor process debate.'

The grounds for a '*New Division of Labor*' (Littek and Charles, 1995/reprint 2011) arose from a number of far-reaching changes in the markets, a new quality of competition, and growing pressure for flexibility and for customer services. Toward the end of the twentieth century, this was labeled by some scientists as the 'end of mass production.' Cost-reduction, higher efficiency, and quality-gains were sought in 'lean production.' Also, it was found out more and more that hierarchical command structures tend to be not utterly effective in a volatile economic environment. The more it becomes necessary to trigger creativity and to improvise in the workplace, the more democratic, as a rule, cooperation becomes. The thourough digitaliszation of work life in the last decades has enormously facilitated and accelerated such processes.

Elements that have gained in importance in leading business enterprises for doing one's job are decentralization, networking, quality circles, upgraded skills, motivation, self-organization, outsourcing, and autonomy of subunits of an enterprise. Even internally, competition and market principles instead of rigid prescriptions from the hierarchy get employed to coordinate the single work tasks in the division of labor. All of these bring responsibility back to the work floor. These are conditions based much more on trust as a means of coordination of partial work tasks. Of course, and this has to be underlined, all these new forms of organizing the labor process are ultimately steered by the search for excellence of performance under the overriding goal of optimal profit-making. That creates a built-in pressure not only in the highly competitive national and international environment but often just as well within the single enterprise and its subunits.

Globalization and International Division of Labor

Today, division of labor in practically every country is also greatly affected by the globalization of economic activities. The international division of labor has changed tremendously. A 'world economy' in which capital accumulation proceeded through the world has existed in the West at least since the sixteenth century. But, historically new, since the late twentieth century, is the emergence of a 'global economy.' This 'global economy' has the capacity to function as a unit in real time on a planetary scale. It is based on the new infrastructure provided by information and communication technologies.

A number of essential elements are present. First is that capital is now managed around the clock in globally integrated financial markets working in real time, which gives it a 'hypermobility.' Second, labor has become, in several respects, a global resource: firms may choose to locate in places worldwide to find the labor supply they need (be it in terms of skills, costs, or social control); firms almost everywhere may also solicit needed skilled labor from everywhere; and labor will enter any market on its own initiative, from wherever it originates. Third, markets for goods and services become increasingly globalized. Production processes incorporate components that are produced (or designed, or sold) in many different geographic locations by different firms (e.g., Castells, 2000; Vallas, 2012).

As a result, working conditions and the division of labor have changed massively. The opening up of markets has made it possible for large corporations to relocate substantial parts of their business operations overseas, with drastic reduction of work opportunities in the home countries. Even more pronounced have been the effects on working conditions in the developing world, where female and male workers seldom receive any labor protection at all (Vallas, 2012; Mies, 1999). In sum, the spatial division of labor quasi has exploded within a few decades.

Division of Labor, Social Differentiation, and Cohesion

Social differentiation is so closely connected with the division of labor that both could almost be treated as synonymous. The growing complexity of the division of labor under modern industrialism and postindustrialism caused a similarly wide expansion of social differentiation in society. Along with this expansion, social and economic interdependence has increased enormously: Each individual in society is dependent on so many others for his or her existence (*see* Differentiation: Social).

Social differentiation itself embraces various aspects of which the more important ones shall be examined:

1. As a major element in differentiation, gender remains a cause for inequality. Even though patriarchy has lost ground and equal opportunity rights are enforced in most modern societies, the effects of a gendered division of labor are still to be found in practically all societies. These often include lower income, confinement to less demanding jobs, reduced access to leading functions, broader employment in precarious jobs, part-time work, and so on.

On the basis of social policy programs, the chances for equal employment in many countries have improved in recent

decades. But, studies have found that a multitude of factors so far prevent the arrival at definite equal opportunity (Lundberg, 2010; Vallas, 2012 – for USA). Also, most societies differ significantly in their specific 'gender culture' (Pfau-Effinger, 2004 – for Europe; *see* Gender, Economics of). This continuing actual discrimination is explained by the fact that the household continues to be the basic social unit around which people conduct their lives, and an unequal distribution of tasks in household and public employment between women and men continues to be practiced, more or less, throughout the world (e.g., Pahl, 1988; Mies, 1999).

2. Class and social stratification are likewise closely connected to the division of labor. They are relevant as a precondition, as well as a result, of the division of labor. With regard to class, most social scientists would agree that the number of classes needed to describe the social structure in modern complex societies has to be extended beyond the two basic ones (bourgeoisie and wage labor) (*see* Class: Social). Marx had in mind. Often the concept is replaced altogether by social stratification. Nevertheless, ownership of productive property is important as a precondition for the right to organize labor, or otherwise being organized. Between the higher and the lower strata, there exists a strong fragmentation from an elitist core to outright precarious jobs or even unemployment. The gains from ones economic activity, however, shape the wealth distribution. As a result of the differentiated division of labor, the inequality of the wealth distribution is increasing in most countries over time (e.g., Standing, 1999; *see* Inequality, Social; Social Stratification).
3. Finally, social integration and cohesion become much more important with the growing diversion and inequality that follow the extension of the division of labor (*see* Integration, Social). Cooperation and coordination are necessary to counterbalance the diverging forces and to secure at least a minimum of social integration (*see* Cooperation: Sociological Aspects). Social integration on the societal level is based, above all, on two institutions: trust, solidarity, motivation, and shared values on the one hand, and power on the other. (Power is based on legitimacy in modern states, not merely on coercion.) Due to the vast increase in the division of labor with the rise of modern industrial societies, a change from 'mechanical solidarity' to 'organic solidarity' as a basis for social integration has been prominently outlined by Emile Durkheim (1893/English 1984; *see* Solidarity, Sociology of). In most highly developed countries the strategy nowadays is to secure solidarity and shared values along with legitimate power: First, a more or less powerful social policy aims at providing a minimum of social security, and second, some form of social regulation is applied against too harsh effects of the market economy. Thus, a socially responsible division of labor (as an important aspect of sustainability) may be seen as the guiding vision for modern countries.

Division of Labor in Social Thought

Because the division of labor is a fundamental structuring principle of societies and has so tremendously changed especially in the last 200–300 years, it has played an important role in theories about society and social change. Interest in division of labor was particularly strong in the eighteenth and nineteenth centuries, when the unprecedented change from traditional agrarian to industrial-capitalist societies occurred. That was also the time of the formation of political economy and sociology. Later, the division of labor as a category in social theory was somewhat neglected. But, in the last few decades, interest has risen again, mainly due to

- a broad expansion of studies into women and work, the sexual division of labor, paid and unpaid employment, and the role of women in society (*see* Gender, Economics of);
- studies on the globalization of work and its new division because the world economy in general has grown increasingly global, production networks now stretching across national boundaries and continents, with effects on working conditions in literally every country; and
- studies on the increased pressure for labor flexibility and precarious jobs in the new economy, which indicate a loss of dependable employment conditions and of elements that formerly structured work like defined time, space, acquired skills or occupation, or tenure (*see* Work and Industry, Sociology of; Work, Sociology of).

In the history of theory on the division of labor, contributions from a number of key authors ought to be mentioned (*see* Division of Labor: History of the Concept):

1. Ancient Greek philosophy, and particularly Plato and Aristotle, recognized the necessity of a functional division of labor, reasoning that individuals have different natural capacities, but together are able of producing a harmonious whole. Economically as well as politically, this is of advantage for the social welfare of the state. The socializing effect similarly stood in the foreground for Aristotle when he noted that no society made up of only two physicians could emerge, but a society containing a physician, a farmer, and a few other occupations would be able to exist.
2. At the beginning of modern times, Adam Smith (1723–90) is of the utmost importance for the development of the discipline that became known as political economy. No one has ever placed more emphasis on the division of labor. But, whereas for Plato the level of specialization was externally determined (by the natural inequality of human abilities), division of labor for Smith is the most effective factor for driving economic progress. In his book '*An Inquiry into the Nature and Causes of the Wealth of Nations*' (1776), Smith explored the possibilities for raising productivity along two avenues: the detailed division of labor within the manufacturing process and the liberalization of markets in the economy as a whole. He recognized the egoistic pursuit of individual interests as the driving force of economic activity, which is coordinated by the 'invisible hand of the market.' But Smith also recognized that the breakdown of a production into specialized subtasks carried the danger of 'mental mutilation' of the workers being confined to a single repetitive task.
3. For his contemporary Adam Ferguson (1723–1816), under the impression of the upcoming new commercial civilization, social differentiation through the division of labor and

occupational specialization stood in the foreground. He considered the division of labor as a specific structuring activity for human solidarity, but also the concept of alienation is prefigured in his work. Thus, his views became influential for Marx and Durkheim later on.

4. Both the economic and the social aspects of the division of labor were analyzed by Karl Marx (1818–83). He developed much of his work as '*A Critique of Political Economy*' (this is the subtitle of his seminal publication '*Capital*,' Vol.1, 1867). In a way similar to the classical theorists, Marx elaborated the enormous potential of division of labor for productivity in manufacture and in big industry. But, although drawing on very similar insights, he came to different conclusions. He emphasized that there is a fundamental difference between division of labor among autonomous parties ('division of labor in society') and division of labor taking place under the authority and in the interest of one dominant party ('division of labor in manufacture'). The contrast between 'anarchy' of the market and 'despotism' in the workshop was highlighted by Marx as an essential feature of the 'capitalist mode of production.' He was also strongly concerned with de-skilling and alienation of workers as a result of the specific fragmentation and domination of work in manufacture.
5. Emile Durkheim (1858–1917) directed attention mainly to the sociological aspects in his '*The Division of Labor in Society*' (1893) for which above all he gained reputation. In contrast to more pessimistic views, he recognized that the fragmentation and specialization inherent in the division of labor does not have to create social disintegration. Durkheim's argument was that in small-scale societies, with only a limited division of labor, people were bound together by 'mechanical solidarity.' More complex modern societies, on the other hand, are bound together by 'organic solidarity,' as their advanced division of labor acts as the basis for much interdependency and bears a greater potential for social integration based on more individual rights. As a threat inherent in the modern development, he observed the danger of possible 'anomie' and of a 'forced division of labor' in a society.
6. In his analysis of the modern (Western) world, Max Weber (1922) (similar to Marx) worked out the specifics of the capitalist division of labor. He also emphasized the role of private property, profit as the motive for production, and the application of rational organizing principles. However, he emphasized different aspects. Weber was interested mainly in fundamental prerequisites of 'modernity' among which legitimate power and 'rationalization' of all spheres of social life (including dependable rational administration in the form of 'bureaucracy') are of importance, as contrasted to incontrollable and personalized execution of power in premodern societies.

Abstract

Labor geography has been shaped in a 'dialogue' between social theory and empirical studies that encompass the real-world experiences of contemporary labor geographers. Three themes recur in debates on this subfield: the agency of labor, constraining and enabling structures, and spatiality. In reviewing these themes, the authors present studies undertaken by labor geographers.

Introduction

As conceptualized by Andrew Herod in the mid-1990s, there are two distinctively different ways of studying labor in human geography. One takes a passive approach to the agency of labor, as exemplified in both neoclassical economic geography in the 1960s and 1970s and Marxist economic geography in the 1980s. The neoclassical approach treated labor merely as an input factor, while the Marxist approach saw workers as reactive agents or a pseudo-commodity, subject to the dynamics of capital accumulation (Herod, 1997). To emphasize their passive views of labor, Herod refers to these approaches as geography of labor. Labor geography, on the other hand, brings labor to the forefront and marks a shift in focus from understanding and representing the interests of capital to understanding and representing the interests of labor. Labor geography examines labor as an agent that acts intentionally and proactively for its own benefit and is capable of shaping the economic geography of capitalism based on its self-reproduction on a daily and generational basis. Moreover, based on the notions that labor is not only local, that capital is not only global, and that space can be a source of power, labor geography provides an approach to place, space, and scale that can explain the plight of workers and opens the way for analyses of contestation and resistance.

Labor geography is a normative discipline that has engaged a number of activist scholars. Over the years, it has widened its thematic approach to cover most significant debates in human geography (Wills, 2009).

Jonas (2009) distinguishes between two main strands of labor geography. One strand is primarily concerned with 'labor as an economic and political agent for itself,' while the other is concerned with the structures and constraints under which labor exists 'despite itself' (Jonas, 2009: p. 62), addressing how workers experience the labor market and are affected by, and respond to, economic restructuring and labor control regimes. When these strands are taken together, the main topics in labor geography are the mobilization of labor, the labor market, and the labor process. Emerging interests in embodied work and emotional labor form part of the latter. While labor mobilization clearly attracts attention to agency, the topics of labor market and labor process point to structures and constraints. However, as labor geography has developed, these themes have become integrated.

Here, the authors review themes and concepts that have characterized the development of labor geography. They first explain the agency of labor in the making of economic landscapes. Second, they review work on the constraining and enabling structures that condition the agency of labor, focusing on processes of flexibility and intensification of work; gender, class, and ethnicity dynamics; labor regimes; and global value chains and production networks. In doing so, the authors draw on geographical work preceding labor geography proper, as well as more recent efforts to view workers' agency as embedded and variegated. Finally, they highlight how geographers have used spatial concepts to develop sophisticated arguments about labor and its prospects in a globalizing economy.

Agency of Labor to the Forefront

Herod proposed that workers are in fact active agents in the making of economic landscapes (Herod, 2001a), and he has explored this proposition empirically through several studies. For example, he has shown that workers and their organizations have been pivotal in determining where economic activities such as offloading containers were to be done (Herod, 1998). In other studies, he found that local worker mobilization in a single plant could have global effects on entire production networks (Herod, 2001b). Herod and other geographers have documented that labor is an active agent in the political economy.

Most empirical studies of labor geography are case studies of particular trade union struggles. A noteworthy example is the attempt of Battersea and Wandsworth Trade Union Council's Organising Centre, a multiunion initiative in Southwest London, to move away from traditional industry-specific organizing toward a territorially defined community activism in the early 2000s (Wills and Simms, 2004). Another is Tufts' (2007) study of hotel unionism in Toronto, where Local 75 of UNITE-HERE combined local and international tactics to enforce pattern bargaining in a metropolitan hotel market. Unqualified success stories are few; nevertheless, the studies convey how a defined group of organized labor (e.g., in a local

campaign) manages to achieve certain gains through mobilizing in innovative ways. This focus may be explained by the fact that many labor geographers are also dedicated activists who nurture long-standing engagements with unionists and take part in political debates about the need for political reform in the union movement. By providing examples that function as inspiration for other workers and activists, they run the risk of depicting labor as a 'freer agent' than is the case for most workers of the world.

While labor geography has come some way in exploring the agency of labor in its expression through trade unionism, labor geographers have only recently started exploring other, less organized and more individualized forms of agency. Among the exceptions is Rogaly (2009). He uses the experiences of Indian short-term migrants to explore individual worker strategies to negotiate the terms of work and employment. Still, nonunionized workers, workers in the informal sector, and labor migrants have yet to attract the level of rigorous analysis that organized labor has received.

While workers may have agency to make small, yet important, improvements in their everyday working lives, Mitchell (2011) argues that labor geographers have overemphasized the power of workers to effect structural changes of the kind that affect the economic landscape. Hence, studies of the structures under which workers live and work are important to uncover how forces within capital and the state may be served by workers' powerlessness.

Structural Constraints and Enabling Structures

Labor geographers now increasingly emphasize that the agency of labor is subject to structural constraints that vary according to context. Doreen Massey's work in the 1980s can be considered a forerunner in this respect (Peck, 2013). Her approach to labor, capital, and the state in explaining economic restructuring and job loss is relational and based on a critical reading of political economy: the geography of industry is an object of struggle, the world is not simply a product of the requirements of capital, and labor is both a locational factor based on its price and an active agent shaping investment decisions (Massey, 1984). This way, labor shapes the economic landscape.

Also, applying a political-economy approach, Jamie Peck inspires a new generation of geographers. His critique of mainstream labor market (segmentation) theory and his emphasis on contextual factors in explaining working conditions and unemployment make 'Work-Place: The social regulation of labor markets' (1996) a watershed. When neoliberals seek to construct labor markets as commodity markets, their powerful discourse is designed to ease deregulation and flexibility. Building on Marx and Polanyi, Peck stresses the social nature of human labor and productive activity and emphasizes the placeness of work. Structural constraints are prominent in Peck's work. However, stressing that labor markets are situated in different regulative contexts should inspire work on enabling structures that have been underemphasized in labor geography so far.

The last three decades have witnessed intensification of market rule, keener competition, and thereby enhanced commodification of labor. Labor geographers delve into how intensification of work and greater demands on flexibility including increased subcontracting and offshoring of work affect labor in terms of access to work, changes in the work process, working conditions, employment conditions, and how agency is put to work. They are also concerned with opportunities and efforts taken to counter or ease negative effects of increasing competition on access to work, wages, and working conditions (Coe et al., 2009).

Labor geographers have undertaken extensive research on labor market intermediaries, such as temporary staffing agencies. A prominent example is the work of The Geographies of Temporary Staffing Unit at the University of Manchester. This research group is analyzing and mapping the undertakings of this industry, including its worldwide expansion, the way in which it seeks to shape labor markets, its impact at various geographical scales, as well as various attempts at regulating its activities (Coe et al., 2009). Acknowledging that traditional trade unionism is ineffective in parts of the 'new economy,' Brenner and Dean's (2000) study of Silicon Valley investigates new forms of labor organization and employee representation in a context where nonstandard employment has become the norm. In a study of postapartheid Namibia, Endresen (2010) demonstrates how employers, by recruiting temporary workers through labor market intermediaries, may distance themselves from responsibility for their workers and spur worker alienation.

Gender, Class, Ethnicity

A body of the 'structural-constraints strand' in labor geography delves into gender, race, and ethnicity. While gender relations were integral to industrial relocation in Massey's 'Spatial Divisions of Labour' (1984), Hanson and Pratt (1995) develop this further by problematizing gender-based occupational segregation in a study of workplace–domestic sphere relations in Worcester, Massachusetts. They examine how structures of employment opportunity are constructed in place. Local norms and discourses on gender identities such as familial responsibilities and women's capabilities to work, as well as racial differences, are central to this. While women have agency to move both in terms of identity and space, analyses of containment and mobility show how difficult this is for women in their study area. In another study exploring what poststructuralist theories and discourse analysis can bring to theories of labor market segmentation, Pratt (1999) shows how discourses on Filipina workers in Vancouver reinforce their marginalization in the labor market. Hanson and Pratt (1995) argue that the experience of being a woman depends on positionality, in terms of, for instance, class, race, and religion. This notion is further developed in Linda McDowell's work on the intersectionality of gender, class, and ethnicity and in her studies of embodied forms of work in the service economy. Applying an 'intersectionality approach' in studying migrants, McDowell et al. (2007) explain hyperexploitation and labor segregation at a hotel workplace in London and how employee identity becomes subsumed within the workplace, effectively limiting opportunity for resistance.

Labor Regimes

Labor regimes are understood as a complex of institutions, rules, and practices through which relations between labor and capital are regulated, both at the workplace and in society at large. Hence, labor geographers' analyses emphasize place, space, and scale and are concerned with how conditions outside the workplace influence how labor responds to poor working conditions (Jonas, 1996, 2009; Kelly, 2002; Knutsen and Hansson, 2010).

As defined by Jonas (1996, 2009), the concept of local labor control regime represents a shift in explanatory focus away from the politics of *work*places to that of work*places*. Jonas's analyses of the sphere of reproduction stretch to the politics of the place of residence and the politics of consumption. Formed by local conditions as influenced by extralocal institutions and regulations, local regimes reflect practices constructed in places. Underlining these arguments, Kelly (2002) found, in a study in the Philippines, that local regulatory regimes differ from national ones as they are mediated through a range of institutions and that the relations that constitute local labor control regimes are informal and fluid.

Labor in Chains and Networks

Recent theorizing aims to reembed labor as an active agent in the concrete landscapes and structures circumscribing their role as change makers (Cumbers et al., 2008; Coe and Jordhus-Lier, 2010). This has included studies on labor in global value chains and global production networks where the ability of workers and groups of workers to engage in decision making around their work and employment have often been seen as limited (Riisgaard and Hammer, 2011). Within the global production networks framework, Cumbers et al. (2008) demonstrated a way to unpack the agency of labor and distinguish between the collective and the individual agency of labor.

In the global value chains approach, Hale and Wills (2005) were among the first to treat labor as active agents embedded within structural constraints and enabling structures. They demonstrate how labor is affected by organizations of production in global supply chains more generally, regarding industrial upgrading as well as labor standards. In order to address working conditions, they consider it vital to understand industry structure, management of supply chains, and political institutions. For labor to meet the challenges of globalization, they propose new labor internationalism and new forms of workers' organizations that link workers and trade unions in producing locations to local consumers and activists, as well as consumers and activists in important markets of the final products and in the home countries of the lead firms.

The agency of labor is embedded in the structures of the state and capital, but to develop this further requires that the agency of the state and the agency of capital are also analyzed. Reembedding exercises have particular implications for the classical research subject in labor geography: trade unions. There has thus been an increasing interest in labor unions' links to other structures. Rutherford (2013) focuses on the relations between labor and the state. Wills and Simms (2004) investigate the links between trade unions and other organizations in civil society, whereas Brenner and Dean (2000) and Coe et al. (2009) discuss the significance of the growing importance of labor market intermediaries for organized labor. Cumbers et al. (2008) explain how global union federations become spaces of class struggle that can be co-opted into global production strategies, thereby reinforcing exploitation.

Other studies on labor's agency in chains and networks focus on workers' sources of structural power and associational power and how structural power can be mobilized by associational power (Riisgaard and Hammer, 2011). The structural power of labor arises from labor's location in chains and networks while associational power results from formation of collective organizations. These analyses of power are highly contextualized in addressing the nature of the labor process, capital–labor relations, government policy of labor, and development of collective organization, always with an eye to the international and transnational links of capital and collective organizations. These studies provide concrete examples of how the agency of labor can be put to power in chains and networks and illustrate the cumulative character of labor geography.

Spatiality (of) Struggles

Labor geography has developed in an era defined by globalization and neoliberal hegemony. Within this larger context, labor geographers have contributed to general debates in human geography on the nature of space and place and the concept of geographical scale; these debates emerged from the basic insight that space is socially constructed.

Depictions of globalization often rest on an assumption that global space is reserved for capital while workers live and act locally in place (Castree, 2000). However, global restructuring is characterized by profound reconfigurations of the scalar organization of society. Scaling and rescaling are political processes, a view shared by Swyngedouw (1997) and Kelly (2002), whose particular concern is that geographical scales are constructed strategically, in political struggles for power and control. Thereby, scales are continuously shaped and reconfigured, and the construction of scale becomes a vital part of class struggle. Herod (2001b) was among the first to suggest that the concept of scale was useful as a tool to investigate how trade unions have been able to institutionalize lasting victories across space in ways that counter the geographic unevenness of capitalism. Since then, labor geographers have arguably been among the most influential in developing the concept of scale within human geography. The scalar strategies of labor are not confined to efforts of 'scaling up.' Rather, case studies show how an interdependent set of agendas meet in the more successful cases, where local mobilization, national institutions, and global campaigns can reinforce each other.

Labor geographers thus investigate the spatial dimension of the capital–labor relation; a common sentiment is that labor resistance to neoliberal hegemony cannot be confined to the local scale. Accordingly, labor needs to pay attention to how geography has a constitutive role in class struggle.

No geographical scale is 'the natural' scale at which the capital–labor relation should be constituted (Swyngedouw, 1997; Kelly, 2002), although scale is often formalized, or fixed, such as in the area of trade unionism. Agreements establish at which scales bargaining should take place: the workplace, at local, national, or international levels. Scalar struggles may involve efforts to confine counterparts to manageable scales in order to control and subordinate, but scalar strategies may also be liberating. For instance, workers may 'jump scales' (Jones, 1998), i.e., avoid constraints by engaging at other scales.

Some examples may clarify these arguments. Castree (2000) discusses the construction of geographical scales during the Liverpool dock dispute. Union procedures got in the way of striking dockworkers; their answer was to instigate and coordinate the dispute themselves, outside the formal unions. The dockers thereby transformed a local issue into a global one. The dock dispute is an example of grassroots' internationalism outside formal unions, at the national and global scales.

The many ways in which capital may construct spaces and thereby undermine the collective strength of labor are demonstrated by Kelly (2002) in his study from the Philippines. Alongside the regular spatial labor control strategy of (re) locating production to places with no traditions of unionization, Kelly identifies multiple other facets of spatial control of labor: individualizing negotiations; constructing the workplace as the container for dispute resolution; establishing the industrial estate as a separate, closed space; constructing imagined national/ethnic communities; and distancing workplace from homeplace by using migrant workers – in other words, by confining labor to manageable scales.

Scales may be invoked in scalar narratives as agents provide accounts of dramatic events (Swyngedouw, 1997). Defining the scale at which regrettable events, such as plant closures, are triggered and by whom, is an example of framing. In Bergene's (2007) case, the closure of a Malaysian textile factory in Namibia caused not only a contestation around who caused the closure, but also at which scale it was triggered. In this process, both factory owners and the Namibian government tried to contain the Namibian working class and the unions to the national scale by stressing that upscaling the dispute would jeopardize investments and even retard national development.

Similarly, according to Swyngedouw (1997), different agents may invoke different scales strategically in their attempt to situate and explain social events. Jumping scales thus also entail reshaping the discourses within which struggles are constituted, and the politics of scale is rendered a representational strategy (Jones, 1998).

Cox's (1998) twin concepts of spaces of dependence and spaces of engagement are of seminal importance and of particular significance to the politics of scale. Both labor and capital strive to secure their conditions for survival in particular places, i.e., spaces of dependence. These spaces are constantly jeopardized by ongoing social struggles, impelling agents to construct spaces of engagement, which often entail organizing across space.

The view that labor, particularly unionized labor, needs to widen its spaces of engagement given the global character of capitalism is widely accepted. However, as Castree (2000) notes, the global scale cannot a priori be given priority. In his view, the significance of any given scale is not the result of its 'size,' but rather of the processes operating within and across several scales. Hence, the strategies of labor ought to be multiscalar. The global scale is increasingly important, but this fact does not render local and national scales irrelevant. Researchers should not seek to identify which scale was more important in deciding the outcome of a dispute but rather analyze the ways in which actions at various scales complemented, or in some cases contradicted, each other. Despite these qualifications, the tendencies toward global capitalism have led researchers to call for an upscaling of trade union strategies to the global scale. Widening spaces of engagement through coordinated action by establishing extensive alliances requires building solidarity. When studying acts of solidarity, Johns' (1998) distinction between accommodationist and transformatory solidarity is useful. Accomodationist solidarity accommodates workers to capitalism, whereas transformative solidarity involves questioning capitalist social relations. As such, transformatory solidarity entails a commitment to universal class interests over and above the spatially derived interests that accommodationist solidarity seeks to safeguard.

Conclusion

Put simply, what labor geographers have in common is a desire to enhance knowledge that is relevant to advancing the interests of labor. Research is done for the sake of labor, whether labor's agency is directly or indirectly brought to the forefront of the analyses. As such, labor geography is a political endeavor. In early work, it is easy to discern a distinction between 'labor geography proper,' accentuating the active agency of labor but largely shunning issues of structural constraints, and 'labor geography political-economy style' studying how labor's agency is constrained by capital–labor relations, regulations, norms, and values as a prerequisite to find ways to put agency to work.

In both strands, studies are empirically oriented, seeking understanding through case studies. This orientation has its advantages in the thoroughness with which contexts can be analyzed. However, 'single' case studies make theorizing difficult as one cannot distinguish necessary from contingent or contextual conditions in the same manner as in comparative case studies. Hence, in order to develop and refine theory, labor geographers should increasingly work comparatively as this approach broadens the base from which to infer. Attempts at theorizing work and workers' conditions should be even bolder.

The relational approach of agency as embedded in structures of the state and capital strengthens the case for enhanced emphasis on the structures and constraints that labor faces. Moreover, current approaches to labor in value chains and production networks, as well as current studies on labor in the context of keener competition and intensification of work, suggest that the two strands might blend such that the binary between structure and agency dissolves.

The concept of structures encompasses concrete rules, roles, and social institutions as well as mechanisms and processes underpinning social life. Structures may not only constrain, but also enable. The very structure that enables one actor may constrain another. Understanding the empirical manifestations of this duality demands a continuous deconstruction of the concept of structure, building on social theory that would enrich the field. Moreover, a better grasp on norms and values representing structural constraints and enabling structures calls for more use of discursive approaches in labor geography. As labor geography proper has been preoccupied with the active agency of labor, and the political-economy strand has primarily dealt with structural constraints, merging the two might yield a much-needed improved understanding of enabling structures.

Labor geographers have started to unpack the agency of labor and the state, but more needs to be done on how labor as individual agents relate to constraining and enabling structures. The agency of labor is predominantly seen as a positive force in labor geography. With increasing labor mobility, negative aspects such as racism in the workplace need more attention.

Still little has been done to unpack the agency of capital; for example, it is time to dig into power relations in the formation and implementation of formal regulations at all levels, from the workplace to the international level. Labor geography would benefit from more studies of how workers can influence the state and attain better control of the regulations that affect their work life. More attention to working conditions and agency during crises, as well as to regulatory regimes and the agency of those who are pushed into unemployment, is also called for.

In sum, labor geography is a subdiscipline on the way to maturity, where the defining trait during the formative years, the focus on agency, is still strongly present, but where structural constraints have increasingly gained attention the last decade. This leads to a more intense dialogue with social theory in explaining such constraints, a dialogue that is most explicit when spatiality is on the table. Here is where the major contribution of human geographers to the understanding of work and workers' life worlds is most visible.

Abstract

'Labor history' has two meanings: it denotes the history of labor movements and of the working classes at large. This article discusses the rise of labor movement history in the late nineteenth century, the growth of working-class historiography during the twentieth century, the origins of the current paradigmatic crisis in labor history, the discipline's core controversies, and its current 'globalization.'

Labor history has two descriptions. In a narrow sense it denotes the history of social movements of wage earners, including their leaders, their organizations (e.g., mutual aid societies, trade unions, consumer and producer cooperatives, and working-class parties), and their collective actions (petitions, strikes, boycotts, electoral campaigns, etc.). In a broad sense, labor history comprises the history of the working classes at large, including the history of family life, demography, everyday culture, leisure activities, housing, religion, migration, and so on (*see* Working Classes, History of). In the early phases of its development as an academic discipline since the 1870s, practitioners of labor history predominantly used the narrow concept.

Beginnings

Labor history as an academic practice came into being after the classical Wage Fund theory had become discredited. According to this theory (of which many variations have existed) there is at any point in time a fixed amount of money out of which wages can be paid; it was therefore "plainly impossible, in any given state of capital and population, to bring about any genuine and permanent rise of wages, otherwise than in the slow course of generations" (Webb and Webb, 1897: II, p. 603). Trade union action could thus have two results. Either it would lead to a redistribution of wages from one segment of the working class to another without the total available amount increasing: "the increased wages secured for merely absorb a larger share of the capital, leaving less to be distributed among others." Or, trade union action was more or less useless: "If wages are below equilibrium, a union can raise them, thus doing what ought to be done and in time would be done by the market itself" (McCulloch, 1851: pp. 50–52). In the 1870s the decline of the Wage Fund theory started with criticisms by John Stuart Mill and others.

With the decline of the Wage Fund theory trade unions and strikes came to be seen in a different light. While most scholars previously had considered trade union activities as false in theory and pernicious or futile in practice, it now became a much more serious topic deserving careful analysis, both contemporary and historical. Pioneer efforts were, among others, Lujo Brentano's *On the History and Development of Gilds, and the Origins of Tradeunions* (London 1870), Richard T. Ely's *The Labor Movement in America* (New York 1886), and the *History of Trade Unionism* (London 1894) by Sidney Webb and Beatrice Webb (born Potter).

For a long time two patterns of interpretations were dominant. On the one hand there was the liberal tradition, represented by, for instance, John R. Commons and Selig Perlman in the United States, the Hammonds in Britain, or scholars like Lujo Brentano, Gerhard Schulze-Gävernitz, and others in Germany. They reconstructed the development of labor movements as the history of the civil emancipation – and consequently the integration – of the working class within capitalism.

The other 'classical' tradition was, of course, the socialist approach in its many forms, varying from moderates to radicals, and including people like the Webbs in Britain, Edouard Dolléans in France, Eduard Bernstein and Carl Grünberg in Germany, or Edvard Bull in Norway. What these socialists had in common was their interpretation of labor history as a history of attempts to transcend capitalism – in whatever way.

Both 'classical' approaches emphasized the labor movements' institutional aspects. Classical labor history consisted of the application of the approaches, methods, formats, and styles of the traditional historiography of ideas and politics to the field of labor history. Insofar as it had addressed 'social issues,' it had been an offshoot of economics and economic history; and insofar as it had addressed the movement itself and its organizations, leaders, and ideas, it had been an offshoot of political or intellectual history. Both versions of the classical approach "tended to produce both a model and an accepted version of history, both national and international, which ranged from an informal but not very flexible to a formal and highly inflexible orthodoxy" (Hobsbawm, 1984: p. 4). I should add, however, that some authors were more or less dissident. There have always been historians who paid attention to atypical aspects, for example, Werner Sombart in his essays on the Italian proletariat (1895); John Le Breton Hammond and his wife Barbara Bradby in their trilogy *The Village Labourer, 1760–1832* (1911), *The Town Labourer, 1760–1832* (1917), and *The Skilled Labourer, 1760–1832* (1919), or Ivy Pinchbeck in her book on *Women Workers and the Industrial Revolution, 1750–1850* (1930).

Broad Interpretation

The classical approaches, whatever their precise substance, served as syntheses for large groups of labor historians. These

old syntheses began to be undermined in the 1950s and the 1960s – a process that continued with even greater force in the following decades. In Britain, Asa Briggs, Eric Hobsbawm, Edward Thompson, and others tried to contextualize workers' struggles. As Hobsbawm wrote in 1964, these historians accentuated "the working classes as such (… and) the economic and technical conditions that allowed labor movements to be effective, or which prevented them from being effective" (Hobsbawm, 1964: p. vii). Somewhat later, similar trends became apparent in other countries. In the United States, Ira Berlin, David Brody, Herbert Gutmann, and David Montgomery, among others, were pioneers.

In France, where the writers of 'evenemential' (*événementiel*) labor movement history had long been opposed by the followers of the *Annales*, whose structural and serial historiography had largely 'left the people out' (to borrow Raphael Samuel's expression), some rapprochement was, especially after 1968, apparent; that was, however, such a slow process that Perrot felt the need to remark in 1979: "(In French historiography) the study of the workers movement has polarized historians for a long time and eclipsed other problems, such as the development of the working class and its culture. However, this is changing rapidly" (Perrot, 1979: p. 150). In Germany, the *Strukturgeschichte*, which was founded in the 1950s by Werner Conze and others (and which incorporated some elements from the National Socialist *Volkssoziologie*, including its focus on the 'structured totality' of the social 'order'), was modified and transformed into a modern approach combining Weberian and Marxian elements by Hans-Ulrich Wehler, Jürgen Kocka, and others since the late 1960s.

Gradually, and especially since the 1960s, a broader approach to labor history has thus become widely accepted. The discipline started to incorporate studies of, for example, social mobility, migration, demography, labor processes, schooling, households, urbanization, social insurance, or sexuality. Race, ethnicity, and gender became generally accepted as essential elements of any analysis, but a full integration into mainstream historiography has not yet been accomplished.

Parallel to labor history's thematic expansion, its geographical scope has widened. Labor history originated in Western Europe and North America, although, early on, there have been important contributions from other parts of the world. From the 1920s it became established in the Soviet Union and later in other Communist countries, and gradually struck roots in Latin America (especially in Argentina, Brazil, and Mexico), Africa (especially South Africa), the Middle East, India, and Australasia. Labor history's present situation is uneven. On the one hand it has become an acknowledged and integral part of historiography in general and of social history in particular. However, on the other hand, its academic conjuncture is strongly linked to political changes, like the collapse of 'socialism' in the Soviet Union and Eastern Europe, and the rise of new workers' movements in Asia.

Both thematic and geographical expansions have made labor history an extremely rich and diversified field. At present, labor history overlaps into women's history, urban history, agrarian history, cultural anthropology, folklore, social economics, history of technology, historical government theories, industrial relations, history of law, and the like. While this disciplinary expansion clearly embodies a wealth of intellectual opportunities, it also leads to a lack of orientation. Already in 1973, Thompson observed that "The central concern of history, as a relevant humane study – to generalize and integrate and to attain a comprehension of the full social and cultural process – becomes lost" (Thompson, 1973).

Conceptual Plurality

Labor history in the broad sense reached its peak during the 1970s when former student militants began to write their theses and books. The productivity of this generation was immense and impressive. Perhaps there would never again be written so much about labor history in so few years as was written at that time. Numerous substantive controversies enlivened the discipline: How should one conceptualize social classes? Are Karl Marx and Max Weber compatible? Is 'labor aristocracy' a useful concept? Have 'organized' labor movements suppressed the interests of unskilled workers? How can one integrate women's history and labor history? What is the societal, cultural, and political importance of the working classes? A wide range of issues were hotly debated, both in professional journals and in the general media.

This peak period did not last long. Most importantly, the organizing categories of the 1960s and 1970s were increasingly called into doubt, partly because they contained continuities with the founding period. Frequently the teleology of the first phase had simply been reserved. While the 'classic' labor historians had been inspired by an optimistic perspective, celebrating the emergence of mass organization and stressing the dynamics of unity and organization, the generation of the 1960s and 1970s tended to ask what had gone wrong with the movement. From a methodological point of view an 'epistemology of absence' became predominant: "Rather than seeking to explain the presence of radically varying dispositions and practices, [labor historians] have concentrated disproportionately on explaining the absence of an expected outcome, namely the emergence of a revolutionary class consciousness among the Western working class" (Somers, 1989: p. 325).

Ever since, many labor historians regard the state of their discipline as a protracted crisis. First, the emerging paradigms of women's and ethnic history showed that there had been giant blank spots on labor history's map and that the filling in of these spots made a complete rewriting of the old narratives unavoidable. And second, the unilinear conception of class consciousness that had been dominant for a long time was questioned. "Once it was established that class was a construction and not a predetermined consequence of structural forces, then the notion that it could be seen as the product of an autonomous culture reacting to certain political and economic circumstances ultimately had to be rethought. Class and class action, it became apparent, could work in many different and contradictory ways" (Price, 1991: p. 253).

As a result of the growing uncertainty about its organizing categories, labor history is beginning to lose its character as a 'discipline.' On the one hand, the distinction with contiguous disciplines, such as women's studies, ethnic studies, anthropology, institutional economics, sociology, or social psychology, is beginning to dissolve, and on the other hand,

conceptual difficulties and political disappointments both have stimulated postmodern approaches, especially in the United States.

In North America and Western Europe, including Britain, the debate between labor historians is therefore dominated by a paradigmatic crisis – a crisis that, as a matter of fact, has apparently not always resulted in a strongly reduced output of the 'older generation' of labor historians, but has often caused a diminished interest among students. In Eastern Europe and the former Soviet Union, the problems are even more serious. The collapse of the so-called 'socialism' has led to the almost complete demise of classical labor historiography, since the latter is with justification perceived as a constituent of the old dictatorship; generally Communist regimes used a distorted 'official' history of the national workers' movement as part of their ideology of legitimation.

At the same time, exciting new developments are taking place. In Latin America labor history is booming (French, 2000), and also in Asia it is rapidly advancing. After a group of Indian intellectuals had already published a series of very innovative collections of essays on the social history of the 'subaltern' classes, which focused especially on the peasants, now a generation of sophisticated labor historians has emerged in that country. Interest in labor history is increasing in several other Asian countries as well, parallel to the emergence of large groups of new wage laborers. Partly, these new labor historians grapple with the same conceptual questions as their colleagues in the rich countries, but that does not prevent their intense research activity.

Core Controversies

There seem to be four interconnected central issues dominating debates within the discipline.

Central Categories

The geographical and thematical broadening of labor history's scope, plus a wider time frame (which now starts to include earlier periods, roughly from the thirteenth century on) makes it necessary to rethink elementary categories, including the discipline's most central notion: labor. In the Anglo-Saxon world, this term has two meanings. It refers simultaneously to work and to workers' movements.

Labor historians have traditionally conceived 'work' as wage labor, performed by legally-free individuals in factories, mines, ports, etc., thus reflecting occupational and gendered views of classical labor movements. Implicitly not included were (1) other forms of free waged labor like domestic service, office work, or voluntary military and police service; (2) unfree waged labor of indentured or otherwise bonded workers; (3) hidden wage labor, for example, through self-employment; and (4) nonwaged labor for subsistance or market purposes. Labor history's broadened perspective suggests a reconceptualization of 'work' as any human effort adding use value to goods and services; use value is understood here as "a good or service that could sustain any activity carried on by a person other than its producer – whether or not we approve of the activity" (Tilly and Tilly, 1998: p. 22–23). This excludes 'purely destructive, expressive, or consumptive acts,' which might be considered as "antiwork" (Tilly and Tilly, 1998: p. 23). Such a Catholic approach makes it possible to overcome old fixations of an institutional or Eurocentric nature.

Traditional labor history has defined a workers' movement as "all of the organized activity of wage earners to better their own conditions either immediately or in the more or less distant future. In all countries it has run along three lines – political, economic, and cooperative" (Commons, 1932: p. 682). A broadening of the concept of 'work' and 'worker' would imply that the notion of a workers' movement has to be broadened as well, and that it should include collective survival activities of all previously excluded categories of workers, whether these are covered by political parties, trade unions, and cooperatives, or not.

Class/Gender/Ethnicity

The relationship between class, gender, and ethnicity has been discussed for several decades. While most labor historians originally considered 'class' as central, and 'gender' and 'ethnicity' and 'race' as categories of a secondary nature, gradually a new consensus has grown which stresses that gender identity, race identity, and class identity have "shaped each other" (Roediger, 1993: p. 131). But despite this new understanding, the *simultaneous* historical analysis of the three identities has proved to be extremely difficult. Following Curthoys one is tempted to see a fundamental indeterminacy problem here: "Trying to keep just two of these concepts in play has proved extremely difficult. […] But if keeping two such concepts in play is hard enough, look what happens when the third concept, be it ethnicity or class or sex, is brought seriously into play. The system, the analysis, becomes too complex to handle" (Curthoys, 1991: p. 15).

Structure versus Actor

A second fundamental indeterminacy problem has a strong influence on labor history debates as well: the relationship between the actor-oriented and the structure-oriented perspective. Classical labor history focused primarily on the agents of social changes: workers, their organizations, and leaders. More recent approaches have paid much attention to broader developments, like, for example, demographic shifts, socioeconomic structures, or governmental bureaucracies. Although few would contest that both modes of interpretation are essential for labor history, their integration is highly problematic.

Even authors who try to combine the two levels (e.g., by paying equal attention to the *longue durée* and short-term events), have to accept that they are in fact telling two separate but combined stories instead of constructing one integrated narrative. The more a scholar focuses on one aspect, the more he or she tends to lose sight of the other aspect. Elton once observed: "Despite attempts to deny this, it [quantitative history] can effectively operate only by suppressing the individual by reducing its subject matter to a collectivity of human data in which the facts of humanity have real difficulty in surviving" (Elton, 1983: pp. 118–119). The reverse could be said as well.

Great versus Small Stories

Classical labor history interpreted the history of working classes and labor movements against the background of major long-term material and cultural changes: for example, the general process of modernization or the rise of capitalism. Since the 1970s this perspective has been challenged from at least two sides.

First, there has grown a strong tendency to criticize such broad interpretative frameworks as 'centrist.' It has been argued that such a way of seeing "positions historical phenomena either to the center or the margins of the historical process, according to their supposed role in the 'great transformation.' " Against this unilinear approach, the critics juxtaposed the emphasis on experiences and processes that do not fit in general schemes. Such a 'de-centered' research strategy is expected to lead to "a greater awareness of the uniqueness, difference, and otherness of historical phenomena, something which is rather obscured by the application of universalizing, passepartout categories (such as role, economic growth, bureaucracy)" (Medick, 1987: p. 82).

Second, classical labor history has been disputed by the so-called 'linguistic turn.' This point of view claims that the backgrounds and interests of the members of a workers' movement cannot explain its development. Instead the language used by the movement's members should be considered as the driving force, as "a complex rhetoric binding together, in a systematic way, shared premisses, analytical routines, strategic options, and programmatic demands" (Jones, 1983: p. 107, cf Scott, 1988: pp. 53–67). Discourse analysis therefore replaces the study of larger material and cultural developments.

Both challenges have directed scholarly attention to previously neglected aspects of labor history. But they have also contributed to the discipline's fragmentation. If discourse is disconnected from its context and considered as 'non-referential' (Jones, 1983: p. 22), or if the concept of historical master processes is contested, then labor history becomes the study of disjointed processes and texts, confirming the lack of a 'central concern' deplored by Thompson (1973). An alternative way of developing labor history further might be through maintaining the idea of master processes and of the contextual situatedness of discursive activities, but by simultaneously taking 'non-central' and linguistic aspects seriously (Kocka, 1997).

Globalization

While the development of labor history is so problematic and uneven, in addition and in connection to this, another trend is apparent: the strong increase in the need to go beyond the national boundaries. The more we know about the history of the working classes in an increasing number of countries, the more tempting it is to place the various national developments in a broader context. Two basic reasons for this can be put forward.

In the first place, we can only discover what is specific and what is generic in our own history by looking beyond national borders. A second important reason for the crossing of national borders is that the object of the investigation is hardly concerned with these borders. Working-class formation is not neatly restricted to certain national borders, but is a process in which voluntary and forced immigration and emigration have a great influence. Dramatic developments in one country may cause turbulences in other countries; strike waves often have a transnational character; new forms of campaigning are imitated elsewhere; national labor movements communicate with each other, learn from each other, and create international organizations.

The growing need for studies that look beyond national borders has resulted in a tremendous growth of the number of contributions to transnational labor history, which started in the 1970s. Yet the work of most labor historians is still characterized by a distinct 'methodological nationalism' that prestructures their writings, with an often rather strict separation of studies of the United States and of other countries.

Labor Market Institutions and Labor Market Outcomes in Transition Economies

Abstract

In this article we study whether labor market institutions matter for labor market performance using a new and unique dataset that covers the countries of Eastern Europe and Central Asia, which in the last two decades experienced radical economic and institutional changes. We show that institutions indeed matter and that deregulation of labor markets improves their performance. We also find several significant interactions between different institutions, which are in line with the idea of beneficial effects of reform complementarity and broad reform packages.

Introduction

This article is on the evolution of labor markets and labor market institutions and policies in the countries of Central and Eastern Europe as well as of Central Asia over the last two decades. As the dynamics of labor market outcomes in these transition economies (TEs) has drawn considerable attention already in the early years of transition and resulted in a voluminous literature easily available elsewhere, this article only briefly touches on this topic. Instead, we focus on the much less explored issue of the evolution of labor market institutions, which are among candidate explanations for the very diverse trajectories of labor markets in the region. We consider recent contributions that attempt to assess the effect of labor market institutions on labor market performance of TEs using unique aggregate country-level data, which we have hand collected.

Labor market institutions have taken center stage in the literature on unemployment ever since the seminal contributions of Nickell (1997) and Layard and Nickell (1999). Employment protection, the unemployment benefit system, and taxes on labor are institutions that profoundly affect wage and price setting in the labor market and thus determine the unemployment rate in the short and long run. The proper design of labor market institutions is thus crucial when pursuing macroeconomic policies that guarantee sustained growth and the highest level of employment possible. Layard and Nickell have taught us that a good design does not necessarily mean that all institutions are as 'flexible' as possible. Instead, the right interplay of institutions, often reinforced with an aggressive stance on active labor market policies, is far more important to guarantee low unemployment. Our work on the role of labor market institutions in TEs contributes to the empirical literature on the crucial link of these institutions and labor market performance.

We look at five labor market outcomes that are of particular interest in the literature when assessing labor market performance: the employment-to-population ratio, the unemployment rate, the long-term unemployment rate, the youth unemployment rate, and the size of the informal sector in the economy. (An early seminal contribution to this literature covering OECD countries is by Nickell (1997) who looks at the first four outcome variables only. Unfortunately, there are no reliable data on informal employment for all the transition economies and we take the size of the informal sector as a proxy for informal employment. (Gimpelson and Zudina (2011) for Russia, Lehmann and Pignatti (2007) for Ukraine show that the two variables are highly correlated over time.) These five outcomes will constitute the dependent variables whose determinants we will analyze in our empirical analysis. The determinants of labor market performance are many; in this article we restrict ourselves to labor market institutions and labor market policies, in particular employment protection legislation, the tax wedge on labor, union density, the level of unemployment benefits, and their duration as well as expenditures on active labor market policies. (For a recent survey of the link between labor market institutions and policies and labor market performance in OECD countries, see Bassanini and Duval (2009).) For reasons discussed below, neither the minimum wage nor wage bargaining is included in the list of determinants of labor market performance in TEs.

Traditional measures of labor market performance are the first four mentioned outcomes, while informality has only recently been linked to labor market institutions and policies in the literature on labor markets in less developed economies (Lehmann and Muravyev, forthcoming). Informality and informal employment pose a major challenge to policy makers in the transition countries of Central and Eastern Europe and the Commonwealth of Independent States. While it is difficult to precisely estimate the size of these phenomena, there can be no doubt that in these areas of the world a large part of economic activity is not registered or only partially registered and that many workers enter employment relationships that provide only partial or no protection against unemployment, illness, and old age (see, e.g., Slonimczyk, 2012, 2013; Lehmann and Pignatti, 2007). Whether labor market institutions and policies have an impact on the size of the informal sector and thus on informal employment is an important but hardly researched topic in the literature. Our work on this topic, summarized in this article, thus provides a unique contribution when trying to answer this question for TEs.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.94032-7

The bulk of the available evidence concerning the impact of institutions and policies on the first four measures of labor market performance is based on data from two dozen OECD countries. Only in recent years have some scholars started to look at the role of labor market institutions and policies in less developed economies (Botero et al., 2004; Feldmann, 2008). To a considerable extent, such interest stems from a much larger variation in institutions and labor market policies as well as in labor market outcomes across such an extended list of countries, both in the cross-section and time dimension. (For example, Djankov and Ramalho (2009, p. 11) state: "Developing countries present an exciting venue for studying the impact of regulatory reforms, including of labor reforms. A number of countries, especially in Eastern Europe, have recently undergone significant reforms to make labor regulation more flexible.") In addition, data from less developed countries, in principle, can help reveal whether the previously obtained conclusions for the OECD economies can be generalized to other regions of the world. However, the potential of non-OECD countries to contribute to the economics literature in general has not yet been fully realized because of only very limited availability of data. In the subset of non-OECD countries that interests us here, the transition countries, changes in labor market outcomes as well as changes in institutions and policies are more marked over time than they are in mature OECD countries (Boeri and Lehmann, 1999), providing thus a natural testing ground of the theoretical considerations that link labor market institutions and labor market outcomes.

The literature on OECD countries highlights the large heterogeneity in labor market outcomes even in the presence of very similar labor market institutions. The explanation for this large heterogeneity is often tied to the complementary nature of the interaction of labor market institutions when institutions are simultaneously liberalized (see, e.g., Coe and Snower, 1997). By analyzing interactions of different institutions and policies we provide some additional support for the complementary nature of simultaneous liberalization of various labor market institutions in the rather different economic context of transition countries. This analysis is, however, only undertaken for the first four labor market outcomes but not for the size of the informal sector.

Macroeconometric analysis of labor market developments using country-wide data certainly has its critics since it has difficulties in pinning down causal effects. Nevertheless, we consider this analysis worthwhile for at least two reasons. First, establishing links between some labor market institutions or policies and measures of labor market performance that are robust across specifications provides some solid evidence regarding the beneficial effects of flexible labor market institutions in the medium to long run. Second, in non-OECD countries the impact of labor market institutions on labor market outcomes, and in particular on informality, has been analyzed nearly exclusively from a labor supply perspective (see, for example, the chapters in Frölich et al., forthcoming). In contrast, our macroeconometric analysis of the determination of the five labor market outcomes also encompasses the labor demand side, at least partially.

The Evolution of Labor Market Outcomes in Transition Economies

In the literature studying the region, it is common to classify countries into three major groups: Central Eastern Europe (CEE, embracing the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovak Republic, Slovenia), South Eastern Europe (SEE, which includes Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Macedonia, Montenegro, Romania, and Serbia), and the Commonwealth of Independent States (CIS, which until recently included 12 out of 15 constituent republics of the former USSR, namely Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, Kyrgyzstan, Moldova, Russian Federation, Ukraine Tajikistan, Turkmenistan, and Uzbekistan with Georgia officially leaving the organization in August 2009). We will for the most part stick to this classification, commenting on smaller subgroups of countries or single economies when necessary and/or important. (In particular, we will split the CIS into European CIS (Belarus, Moldova, Russia, Ukraine), Caucasus (Armenia, Azerbaijan, and Georgia), and Central Asia, separate the Baltic states from the rest of the CEE group, and single out Bulgaria and Romania in the SEE group.)

The data suggest some striking patterns of labor market outcomes in the transition countries during the last decades. The key factor behind this dynamics was the drop in output that these countries experienced at the outset of transition. **Figure 1** presents data on GDP per capita across the subgroups of countries. Although the decline in output was significant everywhere, it was particularly dramatic in the CIS and Baltic states. The group of European CIS also experienced the longest recession. The decline in output could not occur without important consequences for the labor market. As the adjustment mechanisms have been thoroughly studied elsewhere (Svejnar, 1999; Boeri and Terrell, 2002; Earle and Sabirianova, 2002; Lehmann et al., 1999; Lehmann and Wadsworth, 2000), we will only illustrate key stylized facts. The employment-to-population ratio is substantially smaller in SEE than in the other transition regions (see **Figure 2**). It is u-shaped for CEE in the 1990s, indicating an upturn in labor demand in the later part of transition, while in SEE it shows a strong downward trend until 2004. The unemployment rates also exhibit interesting patterns even if we average the rates within regions (**Figure 3**). It is noteworthy that unemployment rates have been higher in CEE than in the CIS for the most part of the period considered even though the employment-to-population ratios hardly differ. The other important feature that should be mentioned is the large drop in the unemployment rate between 2004 and 2008 in CEE and SEE, whereas the unemployment rates drop gently in the CIS. Long-term and youth unemployment rates are far higher in SEE than in the other two transition regions. The largest drop in both rates between 2004 and 2008 can be observed in CEE and SEE.

As far as the size of the informal sector is concerned, it is very high in the CIS, high in SEE, and moderate in CEE. This pattern stays the same over the time horizon that Schneider et al. (2010) consider, namely from 1999 to 2007. In **Table 1** we report this informality statistic from their paper for each country for the years that we use in our empirical analysis. Inspection of the table shows that in 1999 Georgia and

Figure 1 GDP per capita across the subregions of Central Eastern Europe and Central Asia.

Azerbaijan had the highest share of informality with 68% and 61% of GDP, respectively, followed by Ukraine, Belarus, and the Russian Federation. The Central Asian Republics have also high shares of informality. These numbers clearly point to the importance of activities in the grey economy in the CIS. With the exception of the Baltic States the numbers for CEE are relatively modest, in particular for the Czech and Slovak Republics, while the countries in SEE take a middle position. The numbers indicate at any rate that relative to advanced OECD countries the informal sector is of greater importance in TEs. Table 1 also demonstrates that between 1999, a year of recession, and 2007, when we have an economic boom, the size of the informal sector is declining in all transition countries, pointing to an anticyclical pattern of informality in the region. We can thus moot that workers take up informal activities more intensely when the economy is in recession and move more into formal employment in boom times.

Data

Before giving a descriptive analysis of the labor market institutions and policies we briefly describe our data sources. Our empirical analysis is based on data from several principal sources. The first source is the database of the IZA Program Area 'Labor markets in emerging and transition economies,' which is a new hand-collected dataset that provides essential information about the evolution of labor markets in the countries of Central Europe and Central Asia. It includes 27 countries of the region and spans 4 years, 1995, 1999, 2003, and 2007. The database contains four key variables characterizing labor market outcomes and six key variables describing labor market institutions. The latter include employment protection legislation (OECD version II), expenditures on active labor marker programs, tax wedge, unemployment benefit size (measured as average benefit to average wage), unemployment benefit duration, and union density. The details about the variables included in the database can be found in Lehmann and Muravyev (2012).

The second source is data on the size of informal economy taken from the paper by Schneider et al. (2010). This source provides estimates for 162 countries, including Eastern European and Central Asian countries over 1999 to 2007. This is a unique dataset providing comparable estimates for most countries of the world based on the MIMIC estimation method. From this source, we take information on the size of informal economy in transition countries in 1999, 2003, and 2007.

Finally, we have added some key macroeconomic variables from the World Bank database (http://data.worldbank.org/), such as GDP growth rate and inflation. These variables are commonly used in macroeconometric labor regressions for various robustness checks.

General Descriptive Statistics and the Evolution of Labor Market Institutions

Descriptive statistics for the key variables characterizing labor market outcomes as well as labor market institutions is shown in Table 2. The size of the informal economy is large in the region (above 36%), but varies considerably across the countries. The other labor market outcomes are somewhat weaker in the sampled countries as compared with the developed economies (see also Lehmann and Muravyev, 2012). However, there is also considerable variation across the countries and over time. The variables measuring labor market institutions and policies are, in general, at lower levels than in mature market economies, especially of Western Europe. The EPL appears to be relatively rigid, at the level of 2.41. The tax wedge is non-negligible, although less than in most mature market economies. Unemployment benefit is rather small, 25% of the average wage, and much less than in developed countries. The duration of unemployment benefit is 11 months, on average. Again, this is less than in most high-income countries, especially of Western Europe. Union density is at the level of 43%, which is considerable.

Figure 4 shows the evolution of the six variables that proxy labor market institutions and policies for the three subsets of transition countries and, as benchmarks, for the EU15 and the U.S. The index for employment protection legislation is similar among the three regions of the transition area and the EU15 whilst the index is much lower for the U.S., pointing to a difference in employment protection that is of an order of magnitude between the latter country and the other regions analyzed. It is also striking that between 1999 and 2007 the indices hardly change for CEE, the EU15, and the U.S.; in contrast we see a substantial fall in the CIS region. The upper right panel demonstrates a much lower union density for the U.S. and the near constancy of union density in the EU15 and the U.S. while in transition countries we see a large fall in CEE and the CIS. Nevertheless, at the end of the period SEE and the CIS still have a substantially higher percentage of workers with union membership than does the EU15. Tax wedges on labor are high and remain high for CEE, SEE, and the EU15 throughout the period, while in CIS countries it shows a precipitous fall from more than 40% to close to 30%. The introduction of low flat income tax rates in many CIS countries in the first years of the new century seems to have driven the lowering of the tax wedge in this region, approaching the constant low tax wedge that we see in the U.S.

The last three panels show measures of active and passive labor market policies. Only in the EU15 are expenditures on active labor market policies substantial reaching to nearly 1% of GDP. These expenditures are much lower in all transition regions, in particular in SEE and the CIS. There is some slight decrease over time in all regions apart from SEE, which is related to an expanding economy in the latter half of the period. It is also noteworthy that the U.S. spends consistently less than CEE. The last two panels deal with the generosity of the unemployment benefit system. The EU15 has by far the most generous system since a long duration of benefits is combined with a relatively high replacement rate. Among the transition regions SEE is the most generous, the CIS is the least generous since the replacement rates are close to negligible over the whole period and the duration of benefits falls dramatically in the latter half of the period.

Figure 4 demonstrates why we can speak of the U.S. labor market as the archetypical flexible labor market since the measures for EPL, union density, and the tax wedge on labor are all very low. Many researchers link the superior GDP growth of the U.S. economy between 1993 and 2007 to the flexibility of the U.S. labor market. At the same time Figure 4 shows a clear tendency toward a more flexible labor market in the transition region, and in particular in the CIS. We, therefore, ask whether this increase in flexibility has brought with it a better labor market performance, i.e., more employment, less unemployment, and less informality. We now turn to the methodology employed to answer this question.

Table 2 Descriptive statistics

Variable	*Mean*	*SD*	*Min*	*Max*	*N*
Employment ratio (ER)	64.23	8.69	31.20	79.90	97
Unemployment rate (UR)	11.34	6.30	4.00	36.70	79
Long-term unemployment rate (LTUR)	52.66	17.53	14.60	92.60	70
Youth unemployment rate (YUR)	24.84	14.18	7.80	65.70	72

Methodology

Our analysis of the links between labor market outcomes, including the size of informal economy on the one hand and labor market institutions and policies on the other hand, draws heavily on the standard macro-regressions proposed in the seminal study by Nickell (1997). In that study, labor market outcome variables are related, in a panel regression framework, to a set of variables measuring institutions and policies, as well as to the change in inflation. We proceed in an essentially similar fashion by considering, in the baseline specification, six variables characterizing institutions and policies.

We note that our results do not necessarily have a causal interpretation as both institutions and policies may be shaped by labor market outcomes, for example, via the mechanism of elections (Blanchard, 2006). Nevertheless, we try to address endogeneity (at least some of its sources) by controlling for

Figure 4 Labor market institutions in Central Eastern Europe and Central Asia. Source: Database of the IZA Program Area 'Labor markets in emerging and transition economies.'

omitted factors (including unobserved characteristics of countries) by using random- or fixed-effects specifications of our regression model. These are necessary as the paucity of the degrees of freedom does not allow inclusion of many potentially relevant explanatory variables. The baseline regression eqn [1] can then be written in the following way:

$$LMO_{it} = \alpha_i + \beta_1 EPL_{it} + \beta_2 ALMP_{it} + \beta_3 TAX_{it} + \beta_4 DENSITY_{it} + \beta_5 BEN_DURATION_{it} + \beta_6 BENEFIT_SIZE_{it} + \beta_7 INFLATION_{it} + \beta_8 GDP_GROWTH_{it} + \varepsilon_{it} \quad [1]$$

where index i denotes countries and index t denotes time, $t \in \{1999, 2003, 2007\}$, *LMO* stands for labor market outcomes (As much of the previous studies, we do not apply logarithmic transformation to the dependent variables in the model.), *EPL* measures the strictness of employment protection legislation, *ALMP* is expenditures on active labor market programs, in % of GDP, *TAX* is the tax wedge on labor, *DENS* measures union density, *BENEFIT_SIZE* stands for the average unemployment benefit replacement rate, *BEN_DURATION* stands for the maximum duration of unemployment benefits, *INFLATION* is the change in inflation over the previous year, *GDP_GROWTH* is the cumulative growth of GDP in the 3 years before labor market outcomes are measured, and ε is a white noise disturbance. In addition, we consider a specification which includes time effects that capture common macro-trends in the countries sampled.

As can be seen from the specification of eqn [1], one substantial difference from the study by Nickell (1997) is that we do not include variables measuring union coverage rates and bargaining type – again, mostly for data reasons, but also due to the difficulties in interpreting these variables in less-developed countries. (For example, how would one interpret data on bargaining in a country where trade unions with high membership rates are effectively controlled by the

government? It is therefore no surprise that the World Bank did not provide statistics on the coverage rates and bargaining type in the CIS countries (World Bank, 2005).) We, however, believe that we capture the essential aspects of wage setting with our union density variable since it is regarded as the most important of the related factors (Eichhorst et al., 2008). We also do not include the minimum wage. While its effect on employment is controversial in the literature (see, for example, Card and Krueger, 1994; Neumark and Wachter, 1992, 2008), it certainly affects labor supply and demand in countries where it is binding and enforced. In many transition countries of the CIS the real minimum wage is, however, so low throughout the period that it is far below the subsistence minimum and thus does not influence workers' behavior. In addition, where the minimum wage is not negligible it is often not enforced due to weak legal instruments.

In previous work (Lehmann and Muravyev, 2012), from which we report here, we also looked at the question whether reform complementarities improved labor market performance; that is, whether reforming more than one labor market institution brought larger benefits than confining the reform effort to one institution or policy. There is convincing evidence in OECD countries, at length debated in the literature, which shows that countries with similar single institutions might experience very different labor market outcomes because these single institutions are interacted with other single institutions, which in turn differ from country to country. A classic example of the importance of institutional complementarities is shown in Nickell (1997) when discussing the level of unemployment benefits. Ceteris paribus, a high level of unemployment benefits should imply a higher unemployment rate, but when interacted with a short duration of these benefits and large expenditures on ALMP, the institutional mix applied in Sweden, generous unemployment benefits might result in better labor market performance.

In Lehmann and Muravyev (2012), we add pairwise interactions of labor market institutions and policies to the baseline specification for the full sample of transition countries. Given the low number of degrees of freedom, only one such interaction is inserted at a time. Following Nickell et al. (2005), the interaction terms are defined in the form of products of deviations of the institutional variables from their sample means. This analysis of reform complementarity is done for the first four labor market outcomes, that is, Lehmann and Muravyev (2012) exclude the size of the informal sector from the analysis.

Empirical Results

We present the results of estimating the baseline specification for all five labor market outcomes, employment-to-population ratio, unemployment rate, long-term unemployment rate, youth unemployment rate, and informality in **Table 3**. These results should be interpreted as the medium-to-long-term effects of changes in labor market institutions and policies. The regression in column 1 shows the effect of labor market institutions on the employment-to-population ratio. The results suggest a negative and statistically significant effect of EPL as well as of the tax wedge on the employment-to-population ratio. Column 2 shows the results for the unemployment rate as the dependent variable. The only statistically significant coefficient here is on benefit duration. It has a negative sign, which most economists would consider counterintuitive: increasing the duration of unemployment benefits leads to a reduction in the unemployment rate. (Longer benefit duration makes the search less costly. Longer search in turn might result in productive job matches that last longer than in the absence of longer search. Hence a longer benefit duration might depress the stock of unemployment via smaller inflows into unemployment.) Note, however, that the coefficient is only significant at the 10% level. Column 3 shows the results for the long-term unemployment rate. The results are similar to those in column 2. Among labor market institutions, the only statistically significant effect is on benefit size, which has a counterintuitive negative sign. The results for youth unemployment, reported in column 4, are more in accord

Table 3 Baseline estimation results

	ER	*UR*	*LTUR*	*YUR*	*INFORMAL*

with economic theory. Here, there are two statistically significant coefficients – on EPL and tax wedge. Both are positive, implying that higher taxes on labor as well as stricter EPL are associated with higher youth unemployment rate. The results for informality, reported in column 5, suggest that informal economy expands with higher EPL and shrinks with longer benefit duration. These last results are plausible since stricter employment protection will depress formal employment and thus boost informality. The conventional interpretation of the impact of longer benefit duration, i.e., keeping workers longer in unemployment, gives us smaller flows into informal employment and thus a lower size of the informal sector.

When we use the alternative specification that includes time dummies capturing trends common to all countries of the region, most of the results reported in Table 3 stay intact. Some results are different, however. In particular, we observe a negative and statistically significant coefficient on ALMP in the regression with youth unemployment. This suggests that spending on active labor market policies is effective in tackling the problem of unemployment among the young workers in the countries under study. Importantly, we still observe detrimental effects of a higher tax wedge and a stricter EPL on labor market outcomes in theTEs.

We finally give a qualitative assessment of the issue of reform complementarity in Table 4, which summarizes the results of Lehmann and Muravyev (2012). Raising expenditures on ALMP will have a stronger impact on unemployment and long-term unemployment if the labor market is characterized by a relatively low tax wedge (row 1 of Table 4). This result is intuitively quite plausible. If, for example, an ALMP measure targeted at the long-term unemployed is meant to rebuild their human capital, such a measure will result in larger outflows into employment if labor is taxed less. A similar argument can be made with the interaction of ALMP and EPL. ALMP measures are meant to make the unemployed fit for unsubsidized regular employment. If EPL is relatively unregulated firms will be more willing to hire from the unemployment pool, a result that is shown in row 5 of Table 4. Very convincing strikes us also the complementary effect of lowering the tax wedge and shortening benefit duration also strikes us as very intuitive. According to row 12 of Table 4, this complementarity will boost outflows from long-term and youth unemployment. It is these results that are particularly interesting from a policy point of view, as they imply that broad reform packages in transition countries that tackle more than one institution or policy will result in better labor market performance than reforming only one institution at a time.

Conclusion

There has been considerable heterogeneity in the evolution of labor markets in TEs over the last two decades, especially at the level of separate countries. The countries of the CIS appear by far the most diverse in terms of economic development and labor market dynamics, with increasing divergence in the most recent years.

The set of labor market institutions that TEs had at the beginning of transition was rather atypical of mature market economies, but has changed considerably over the last two decades. There has been considerable liberalization of labor regulations in TEs, more pronounced than in the old EU member states. By now, most TEs have established sets of labor market institutions and policies, which are similar to those existing in mature market economies.

A growing literature suggests the importance of labor market institutions in the determination of labor market outcomes in TEs. This is particularly true of EPL, the tax wedge, and ALMP. Overall, data from TEs suggest that deregulation of labor markets improves their performance. There is also some

evidence (see Lehmann and Muravyev, 2012) from TEs that reforming two institutions jointly or applying broad reform packages will generate larger benefits than a partial reform focusing on a single labor market institution.

This article also provides first evidence that labor market institutions may matter for informality in the transition countries. This is particularly true of employment protection legislation and unemployment benefit schemes. These effects need to be taken into careful consideration when formulating government labor market policies bent on increased formalization of the economy.

Our empirical analysis, which covers the precrisis years, establishes the robust result that more flexible labor market institutions translate into better labor market performance in the medium to long run. The liberalizing agenda pursued by the Bretton Woods institutions, therefore, seems to have some validity for TEs, at least in 'normal' times.

Labor Market Policy

Daniel Clegg, School of Social and Political Science, Edinburgh, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Labor market policy (LMP) refers to a set of instruments through which governments assist individuals facing difficulties in the labor market, especially but not exclusively unemployed people. The scope and nature of government activities in this area varies considerably between developed countries, and has evolved over time. Alongside an extensive literature that seeks to evaluate the effects of LMP interventions, there has been a growing interest in recent years in the determinants of this important component of modern states actions to promote the welfare of their citizens.

Introduction

In modern societies, the majority of the working age population relies on dependent employment for access to regular income, and – arguably – for a sense of identity and full social integration. The ability to find and keep a job in a competitive labor market is thus a crucial determinant of individual welfare, while in the absence of public support all but the most transitory periods of unemployment can quickly lead to poverty as well as a range of other personal problems. A government purporting to promote the life chances of citizens cannot therefore ignore the socioeconomic risks individuals face due to the operation modern labor markets.

In the first decades after World War II, high rates of uninterrupted economic growth and a political commitment to full employment ensured that most workers in developed economies had limited exposure to the risk of prolonged unemployment. Since the early 1980s, however, lower growth and the reassertion of low inflation as the principal aim of macroeconomic policy has resulted in unemployment rising in many rich countries, reaching levels last seen in the 1930s even in periods of cyclical expansion. In parallel, rapid deindustrialization has placed those with low or obsolete skills at heightened competitive disadvantage in the labor market. It is as governments have sought to support these victims of structural economic change, and craft instruments for managing labor market risks at the individual level, that labor market policy (LMP) has become an increasingly significant field of public action.

This article introduces the field of LMP and surveys some of the most important themes in its academic study. It first defines the boundaries of LMP and describes the variety of interventions conventionally subsumed by the concept. It next discusses the evolution of LMP in developed countries, emphasizing the substantial cross-national variation in the scope of government activities in this area as well as some common trends in their development over time. A final section reviews the two major scientific approaches to LMP, namely analyses that seek to evaluate the impact of LMP and those that seek to explain its evolution.

Defining LMP

The variety of public policies that impact on the demand or supply side of the labor market, and thus indirectly on the extent and distribution of labor market risks, is very large. Public policies in areas as different as trade, regional development, taxation, working-time regulation, education, or child care, to name but these, might be considered labor market interventions. By convention, however, the concept of LMP has a narrower scope, limited to policies that incur direct governmental expenditure and are targeted directly on groups facing particular difficulties in the labor market.

While the targeting criterion may be useful in delimiting the field of LMP conceptually, it contradicts actual practice in most developed countries, and leads to certain anomalies in the statistical recording of LMP. For example, whenever youth unemployment has risen sharply, governments have tended to react by introducing large youth employment programs, often involving temporary subsidies for private-sector employers when hiring any person under the age of 25 years. Though such measures have a target group far broader than other LMPs, they are recorded in international data on LMP expenditure and participation on the justification that the entire demographic group can be considered as disadvantaged in the labor market. By contrast, measures that subsidize private-sector employers hiring any person below a certain wage level are excluded from these statistics on the grounds of being insufficiently targeted. This is despite the fact that the beneficiaries of the two types of measure largely overlap, each is presented in public discourse as a measure to combat youth unemployment, and they are in all probability in competition for a share of the same public budget allocation. As governments have in recent years turned increasingly to more general measures of labor cost or wage subsidization (see below), expenditure data based on conventional definitions of LMP may thus give a somewhat misleading impression of declining public support for vulnerable groups in the labor market.

Limiting the definition of LMP to interventions incurring public expenditure also carries implications. In addressing youth unemployment, for example, governments in many countries have in recent years placed as much emphasis on regulatory reforms as expenditure measures. New types of employment contract with extended probationary periods are an instance of public policies very directly addressed to the problems facing groups disadvantaged in the labor market but using other policy levers than monetary investments and incentives. Indeed, the issue of employment protection legislation (EPL), and its interaction with expenditure-based LMP, has been central to recent debates around the management of labor market risk, particularly in Europe (see below). While

there may be good intellectual grounds for excluding EPL, or minimum wage legislation, from the formal definition of LMP, it is important to acknowledge that these regulations are equally crucial institutional determinants of labor market performance.

Despite being in some senses overly restrictive, the conventional definition of LMP still encompasses a range of very different public policy instruments. EUROSTAT (2006) identifies three broad types of action, which it calls LMP 'services,' 'measures,' and 'supports.' LMP services refer essentially to the intermediation work of the public employment service (PES), including publication of vacancies and referral of jobseekers as well as more intensive case-management work with unemployed people. Also focused on facilitating transitions from one labor market status to another, LMP measures designate a series of more interventionist policy instruments, including programs involving the direct creation of additional jobs for the unemployed in the public and parapublic sectors and subsidies to private employers that seek to incentivize recruitment of disadvantaged groups. Training programs that aim to enhance the employability of disadvantaged groups through instruction in formal educational contexts and/or in workplaces are a third important type of labor market measure, a category that also includes job sharing schemes, support for unemployed individuals seeking to start their own business and specific measures of occupational rehabilitation for those with reduced work capacity due to illness or disability.

Rather differently, LMP supports provide individuals with cash transfers to compensate them financially for economic disadvantage resulting from their labor market situation. The most important type of support is provided through unemployment compensation, including both unemployment insurance (UI) benefits that are paid to eligible unemployed individuals up to a maximum duration of unemployment, and unemployment assistance (UA) benefits that are paid to those who remain unemployed thereafter or who are not eligible for UI in the first place, for example due to an inadequate work or contribution history. The UI benefits to which an individual is entitled is often related to their previous earnings in employment, while eligibility for UA benefits depends on a means test, meaning the income and assets of an individual, or their household, must be below a specified level to allow them to receive support.

Three additional types of financial compensation for disadvantaged workers are also generally considered to belong to the category of LMP supports. The first are one-off lump-sum payments that individuals may receive from public authorities (rather than from their employers) in the event of their being made redundant due to adverse economic conditions. The second are early retirement benefits, which compensate older workers assumed to have little chance of finding replacement employment for their total or partial retirement from the labor market, up to the age of their entitlement to a regular old-age pension. In some cases the payment of these benefits is made conditional on the retiree's employer hiring a replacement employee from an LMP target group such as young jobseekers. Finally, LMP supports also include measures that compensate short-time working arrangements or 'partial unemployment' linked to a temporary downturn in a firm's economic activities as a result of cyclical or seasonal fluctuations. These policies, which are seen as a way of preventing redundancies by facilitating working-time adjustments, have been mobilized extensively in many countries in the current global economic crisis.

The categorization of LMP into services, measures, and supports offers an alternative to an older approach to classifying these policies, still favored by the Organisation for Economic Cooperation and Development (OECD), the distinction between 'active' and 'passive' LMP. The notion of active LMP maps onto the EUROSTAT categories of services and measures, and has spawned an acronym – ALMP – that is widely used in the academic and policy literature. Passive LMP, in this approach, refers to instruments that compensate individuals financially for the loss or absence of employment, in other words what EUROSTAT considers LMP supports. Though widely used, the active–passive distinction is problematic in a number of ways. Most obviously, the terms are rather loaded; from the respective synonyms of active (energetic, lively, vigorous…) and passive (flaccid, inert, submissive…), it is clear they carry very different evaluative connotations concerning the desirability of these different types of instrument, all of which are arguably important parts of a balanced LMP portfolio. If the distinction is understood to differentiate between policies that facilitate positive transitions and those that compensate negative situations, then it neglects the fact that payment of unemployment benefits itself helps to assist labor market transitions by giving jobseekers the breathing space necessary to find jobs well-matched to their skills and professional aspirations, with potentially beneficial effects for productivity levels in the economy as a whole (Clasen, 1999). Inversely, many supposedly active policies may result in labor market transitions that are far from positive, placing individuals in dead-end schemes that may be stigmatizing for the individual beneficiary and do nothing to improve their future employment prospects.

It remains the case, however, that the field of LMP covers policy instruments of a very different character. The distinction between 'entitlement' and 'discretionary' policies that is commonly used in the American budgetary process is of relevance here. Any individual meeting the existing eligibility requirements has a legal entitlement or right – enforceable in court if necessary – to UI or UA. By contrast, receiving LMP services, participating in measures or benefiting from other supports, such as early retirement measures, is not usually an individual entitlement. These other types of LMPs are thus generally discretionary measures, where public expenditure determines the scope of individual participation and not vice versa. As such, governments are far more likely to make frequent adjustments to discretionary LMP than they do to unemployment benefits. The peculiar nature of unemployment benefits as entitlement programs also explains why they have more often than other LMPs been considered part of social policy, something reflected in some countries in them being separately administered from LMP measures and services. But understandings of the respective functions of, and appropriate interactions between, different LMPs have also evolved over time in developed countries, with changing socioeconomic conditions and political priorities.

LMP Development in Time and Space

The first LMPs to become established components of government action across developed countries were unemployment benefits. Modern unemployment compensation has its origins in mutual insurance arrangements established in the second half of the nineteenth century, usually by trade unions in particular localities or economic sectors. In the early twentieth century, as part of the gradual construction of welfare states, governments in most developed countries introduced compulsory UI schemes at the national level (Alber, 1981). An exception was the Nordic countries, where UI remains voluntary to this day, provided through funds managed by trade unions but heavily subsidized by the state. This has provided a strong incentive for workers in Nordic countries to join trade unions, and is one of the factors behind the high rates of union density still found in these countries.

Antecedents of the modern PES, a nationally coordinated system of public labor exchanges generally developed alongside compulsory UI, performing a range of functions – registering unemployment, monitoring availability for work, and publicizing vacancies – crucial for the integrity of a public unemployment benefit system. With the exception of sporadic experimentations with targeted public works programs at times of high unemployment – and especially during the Great Depression of the 1930s – up to the mid-1970s the scope of LMP interventions was largely limited in the majority of developed countries to unemployment benefits and labor market intermediation services provided through the PES. A notable exception was Sweden, where an ambitious policy of professional training and support for the functional and geographical mobility of workers was from the early 1950s a cornerstone of the famed Rehn–Meidner model, which sought to balance full employment, price stability, growth, and equity. Partly in response to the success of this model, and partly out of a perceived need to facilitate economic modernization, labor market measures emphasizing professional training and requalification were also initiated on a rather smaller scale in countries such as France, Germany, and Italy during the 1960s (Bonoli, 2010).

As unemployment rose across the developed world from the mid-1970s onward, LMP development entered a distinctive new phase. Experimentation with a panoply of LMP measures began in most countries, often with the intention of limiting the fallout from the abandonment of a commitment to full employment. Many measures involved the direct placement of young or long-term unemployed people in socially useful community employment or in large training programs, both of which had the advantage of enabling governments to make quick reductions in the politically sensitive unemployment rate. At the other end of the age distribution, the 1980s also saw a steep increase in expenditure on early retirement, as governments sought to contain unemployment through reductions in the labor supply of older workers. This so-called 'labor shedding' strategy, which was particularly popular in Continental European countries, enjoyed the support not only of trade unions but also of many employers, for whom it offered the possibility of externalizing the cost of profoundly restructuring their workforces (Ebbinghaus, 2006). Allied to escalating expenditure on unemployment benefits, this expansionism saw LMP come to represent an increasingly significant part of total government expenditure. In Denmark, most spectacularly, LMP expenditure peaked in 1993 at more than 7% of GDP.

The OECD 'Jobs Study' (OECD, 1994), published in the wake of the recession of the early 1990s, called for a new direction to be taken in LMP development, and has been an important influence on policy debates ever since. Focused on the problem of structural unemployment, the OECD started from the premise that "policies and systems have made economies rigid, and stalled the ability and even willingness to adapt" (OECD, 1994: 1). More explicitly than in the past, it established an opposition between the logic of LMP measures and services, on the one hand, and supports, on the other, arguing for the need to shift the focus of LMP from the latter to the former. With respect to unemployment benefits specifically, it also argued that benefit entitlements should be reduced and tighter behavioral controls imposed upon recipients to reduce disincentives to work. The concept of labor market 'activation,' which is variously interpreted as increasing the share of expenditure on 'active' instruments in total LMP disbursements or enhancing the work-related conditionality of unemployment benefits, has its intellectual roots in these propositions. Rhetoric aside, however, the Jobs Study was actually also rather critical of many 'active' LMPs, advocating less emphasis on public sector employment and labor market training relative to job-search assistance and well-targeted subsidies to private employers, as well as a closer administrative articulation of LMP measures with benefit provision. The introduction of competition in LMP delivery, through the development of 'quasimarket' mechanisms in the PES and increased contracting-out to private employment service providers, was also promoted.

The Jobs Study's recommendations have been embraced to differing extents in LMP development over the last decade. There has indeed been a marked shift in the composition of expenditure on LMP measures toward what Bonoli (2010) calls 'employment assistance' and 'incentive-reinforcement' approaches, and up to the onset of the 2008 economic crisis expenditure on LMP measures has also tended to decline, driven on the one hand by unemployment falling back from its peak following the recession of the early 1990s, and on the other by governments turning to more general policies to 'make work pay,' such as the subsidization of nonwage labor costs in all lower wage employment to stimulate demand at the bottom end of the labor market and/or the provision of wage supplements to low-paid individuals through the tax or benefit system. 'Active' and 'passive' LMP have also become much more closely integrated at the level of administration and delivery in most countries (Clasen and Clegg, 2011), while 'contractualism' has gained ground as a principle governing relationships between both LMP beneficiaries and the PES, on the one hand, and the financers and providers of LMP measures and services, on the other (Sol and Westerveld, 2005).

By contrast there has been less-aggressive retrenchment of unemployment benefits than the OECD advocated. Across the older members of the European Union, where the most generous unemployment benefit systems could be found, the net replacement rate (NRR) of unemployment benefits remained broadly stable between the middle of the 1990s and the end of the 2000s (Van Vliet and Caminada, 2012). Though

significant declines in replacement rates were seen in some countries – such as the Nordic states and the Netherlands – elsewhere there were substantial improvements in unemployment benefit generosity, as countries like Italy enhanced their traditionally very rudimentary system of LMP supports. The protectiveness of unemployment compensation arrangements has, however, been challenged by more implicit forms of disentitlement, particularly as the deregulation of fixed-term employment contracts – also advocated in the Jobs Study – has resulted in a growing share of people entering unemployment after only brief periods in work, and therefore not having made sufficient social contributions to be entitled to much, or any, support from UI. Early retirement benefits have also been scaled back substantially since the mid-1990s as concern has grown over the sustainability of unfavorable dependency ratios in a context of rapid aging across the developed world.

If the absence of substantial direct retrenchment of generous unemployment benefit systems in Europe can be partly explained by the political risks for governments venturing down this path, it also reflects a more positive appreciation of their role in contemporary LMP than that articulated by the Jobs Study. This is reflected in the rise of the concept of 'flexicurity,' which has become the European Commission's guiding framework for LMP development in the 2000s (European Commission, 2007). Inspired by the Danish policy system, flexicurity is premised on the potential for combining limited regulation of employment contracts, generous and encompassing unemployment benefits and an extensive portfolio of LMP measures to simultaneously offer flexibility for firms and security for workers, while also avoiding the labor market segmentation that results from restrictive EPL. With the rise of the concept of flexicurity, the combined income and employability security provided by LMP has been celebrated over the job security provided by labor market regulation. At least in principle, flexicurity thus seems to move beyond sharp distinctions between active and passive policies that characterized LMP debates for much of the 1980s and 1990s.

While the preceding discussion has traced the broad trends in LMP development, which are largely similar across developed countries, there are also substantial variations in the intensiveness and profile of government actions in this field. Comparative cross-national data on LMP expenditure, and on distinct institutional indicators such as unemployment benefit replacement rates, can help to illustrate these, although they do have their limitations. Expenditure data must be used with caution, not the least given the classificatory anomalies discussed in Section Defining LMP. Meanwhile, as illustrated in **Figure 1**, NRR indicators that take into account the tax treatment of benefits and additional entitlements that recipients may claim in parallel give a rather different picture of unemployment benefit generosity from gross replacement rate (GRR) indicators, which do not. Whether the reference wage used for the calculation of replacement rates is that of an average worker (AW), as in **Figure 1**, or the more traditionally used average production worker (APW) wage can also influence comparisons, as the distance between the AW and APW wage also varies cross-nationally. Most importantly, though, replacement rates are only one of a range of possible parameters on which the design of unemployment benefit systems varies, and can be assessed.

Qualifications notwithstanding, **Figure 1** demonstrates the considerable cross-national variation in unemployment benefit generosity. In the developed countries shown, NRRs range from three-quarters of average wages in Denmark to merely a quarter in Italy. With regard to GRRs, we see the familiar clustering of the English-speaking countries among a group of less-generous systems, though this is attenuated when taxes and additional benefits are included in the calculation. On the NRR indicator, the two Nordic countries are revealed to be the most generous, in keeping with their highly developed welfare states.

Figure 2 illustrates the diversity in the size and composition of overall LMP expenditure across the same countries. As in **Figure 1** we see a clustering of the English-speaking countries, in a group of particularly low overall spenders on LMP. Denmark stands out as an exceptionally high spender on LMP, something that is furthermore not driven by high unemployment; at 3.8%, the 2007 unemployment rate in Denmark was below that of any of the three English-speaking countries. LMP supports are the biggest category of expenditure in all countries except Sweden and the UK, who are otherwise extremely different in their overall commitment to LMP. In Denmark too,

Figure 1 Gross and net unemployment benefit replacement rates, 2007. Source: OECD benefits and wages.

Figure 2 Labor market policy expenditure by category, 2007. Source: own calculations from OECD labor market policy database.

though, combined expenditure on services and measures is close to expenditure on supports. Denmark and Sweden thus stand out as active welfare states, which nonetheless retain comparatively generous unemployment benefit systems.

Evaluative and Explanatory Perspectives on LMP

A large scientific literature has developed alongside the emergence of ALMP as an increasingly crucial component of government action. Next to descriptive studies that enhance our knowledge of LMP across the developed world, and increasingly in transition economies too (Auer et al., 2008), two discrete bodies of work can be distinguished. An evaluative literature, heavily dominated by labor market economists, has sought to assess the impact of different programs and policy instruments, both at the individual and the aggregate level. An explanatory literature, more grounded in political science and political sociology, focuses on the drivers of LMP development, often seeking to account for the very variable levels of commitment to these policies across developed countries.

The literature on LMP evaluation draws on a diverse and increasingly sophisticated range of evaluation approaches and methodologies. A basic distinction is between micro- and macroevaluations, the former interested in the impact of policies on individual outcomes such as employment and earnings, the latter on aggregate outcomes such as employment and unemployment rates. Individual-level evaluations of LMP were long rendered difficult by the lack of adequate microdata, itself a reflection of an absence of a developed 'evaluation culture' in government, particularly in European countries. This problem is abating with time, however, and a recent meta-analysis of evaluations of LMP measures (Card et al., 2010) was able to draw on 97 studies conducted between 1996 and 2007, many providing both short- and medium-term estimates of the impacts of measures. In line with many previous findings, more positive impacts were reported for job-search assistance measures and private-sector employment subsidies than for public sector job creation. Contrary to the findings reported in the Jobs Study, however, positive effects were also found for some training programs, notably when a longer time horizon was adopted.

An even larger number of microevaluations have been published on LMP supports, and especially unemployment compensation provisions. On the whole these depart from the basic premise of neoclassical job-search theory that unconditional provision of unemployment benefits will discourage or lengthen an individual's job search, prolonging unemployment duration and negatively impacting on employment and earnings. Empirical studies have been able to exploit major changes in the unemployment benefit systems to explore these assumptions. A review of evidence on unemployment duration suggests that although the predicted effects are found in many studies, they are typically modest in size (Howell and Rehm, 2009). Furthermore, it is not certain that unemployment duration is the only relevant evaluation parameter. A systematic review of evidence on the effects of unemployment benefit sanctions showed that while there were often discernible effects on exits from unemployment, impacts on individual earnings and employment were far less positive (Griggs and Evans, 2010). Macroevaluations have also explored the relationship between unemployment benefit provisions and unemployment, mostly using quantitative data on relevant policy parameters and outcomes to compare countries with different benefit arrangements. Given the limited number of countries for which reliable data of these kind exist these studies face a 'small N' problem, making it difficult to isolate the causal impact of unemployment benefits on observed variations in unemployment rates, or clarify in which direction any such causality runs. These studies also typically use only one or a few indicators of benefit entitlement, the choice of which can strongly determine results (Howell and Rehm, 2009).

Macroevaluations of LMP measures typically have a more national focus, seeking to identify the employment effects of interventions net of 'displacement' effects, where a beneficiary returns to work only at the expense of an employed person, and 'deadweight' effects, where a beneficiary achieves a positive outcome that they would have achieved even in the absence of the intervention. This literature takes a generally dimmer view of the effectiveness of LMP measures than work based on microevidence (Calmfors, 1994). Such findings do not necessarily disprove the value of such measures, however, as their intended impacts may be largely distributional. More broadly, if evaluative studies – whatever their design or policy

focus – depart from a narrow emphasis on labor market outcomes to investigate the impact of LMP on social outcomes such as poverty and social inclusion, health and even crime, then a rather richer view of their benefits may emerge.

Alongside the impact of changes in socioeconomic environments, the diffusion of evaluative evidence on 'what works' by international agencies may play some role in shaping LMP development in different national contexts. This is particularly the case in the European Union, where since the late 1990s the European Employment Strategy has been developed as an instrument for the explicit supranational coordination of domestic LMP (Goetschy, 1999). However, as LMP impacts upon the wage labor nexus that is central to social relations in capitalist economies, it is likely that the most important determinants of the scope and nature of LMP cross-nationally are political. Extensive LMP 'decommodifies' workers, making them less dependent on selling their labor power in the market, and thereby enhancing their relative bargaining power. In the broader welfare state literature, the significance for the development of generous unemployment compensation of the 'power resources' of the sociopolitical representatives of workers – social democratic parties and trade unions – has long been stressed (Esping-Andersen, 1990). This argument has recently been extended to LMP more broadly (Swank, 2011), though without any systematic testing of the political determinants of different types of LMP measure, which could a priori be expected to appeal to different constituencies in different ways.

The left power approach is not uncontested in the literature on the determinants of LMP, however. It has been argued that social democratic governments in fact do little to positively influence commitments to LMP when employment relationships are also relatively protected, and a divergence in interests opens up between their core electorate of workers ('insiders') and the unemployed and those more precariously attached to the labor market ('outsiders') (Rueda, 2007). With limited risk of becoming unemployed and existing bargaining power, insiders have little to gain from increased expenditure on LMP supports or measures. Indeed, they arguably have something to lose from such policies, in the form of higher taxes and – in the case of LMP measures, at least – intensified competition from outsiders. While the empirical basis for this argument remains controversial, the insider–outsider framework taps into the often ambivalent attitude of the employed population to the unemployed that has without doubt characterized the politics of LMP throughout modern history.

A different challenge to the left power perspective has come from literature on employers' interests in LMP. It has been argued that in protecting workers from socioeconomic risks, LMPs like unemployment compensation simultaneously benefit employers who rely on risk-taking by workers, and particularly their investment in the highly specific skills required in much manufacturing employment (Estevez-Abe et al., 2001). Employers' in manufacturing – long dominant in employer representation in many countries – could on these grounds be expected to have strong preferences for protective UI. While this claim should perhaps not be overdrawn, more nuanced accounts of employers' positions on LMP certainly add something to our understanding of the drivers of policy development. Faced with the prospect of state intervention in this area employers have worked to shape policy development in their preferred direction, in many countries gaining representation alongside trade unions in parapublic institutions through which the policy sector is governed (Mares, 2003). Where such policy institutions are established, furthermore, employers are likely to be socialized into attitudes that acknowledge the benefits as well as the costs of these policies for firms.

This last point illustrates how the development of LMP is crucially shaped by already existing institutional arrangements. Accounts of such effects – too varied and numerous to summarize adequately here – have generally been provided by detailed studies of policy development in one or a few countries. With reference to the UK and Germany, Clasen (1994), for example, showed how the initial financing and governance structure of unemployment benefits shaped policy reactions to mounting unemployment in the 1980s. Schmid et al. (1992) similarly showed the crucial importance of the financing system for LMP supports and measures, which varies considerably across developed countries, on their deployment across the economic cycle. These studies and others like them help explain why governments facing similar labor market problems, armed with identical evaluation evidence and subject to equivalent political pressures and demands still often make substantially different choices in the field of LMP.

Conclusion

The field of LMP covers a very wide array of instruments through which governments intervene on behalf of citizens encountering difficulties in the labor market. Long restricted largely to provision of unemployment compensation and placement services, government interventions in this area have become increasingly diverse since the early 1980s. While commonalities can be seen in the long-run development of LMP in developed countries, striking cross-national differences in the scope and nature of government action remain. As governments in transition and developing countries build up activities in this field, they can draw on a large evaluation literature that has sought to identify the effects of different instruments. This expansion of LMP in turn provides new empirical cases for researchers seeking to better understand the political and institutional dynamics of policy development in this area.

Labor Supply

Bradley T Heim, Indiana University, Bloomington, IN, USA

© 2015 Elsevier Ltd. All rights reserved.
This article is a revision of the previous edition article by J. Pencavel, volume 12, pp. 8195–8204, © 2001, Elsevier Ltd.

Abstract

Studies of labor supply analyze how individuals' decisions of whether to work for pay, and how much to work, are affected by wages, incomes, and other variables. After presenting some empirical regularities, theoretical models are discussed, including static and life cycle models, individual and household models, and models that incorporate income taxation. Finally, the large body of empirical research is reviewed. Though in some areas (such as the size of the intertemporal substitution elasticity and the impact of the Earned Income Tax Credit) a consensus has emerged, there remains considerable disagreement over the magnitudes of many key labor supply parameters.

In economics, the study of 'labor supply' has come to mean the analysis of work behavior where the questions addressed include: How many hours do people work for pay and what factors affect work hours? What proportion of the population works for pay and what factors affect this proportion? The first question, about the number of hours or weeks that individuals work in the labor market, concerns the intensive margin of work. The second question, whether people work or not, concerns the extensive margin of work. The extensive margin may be measured by the employment–population ratio or by the labor force participation rate.

The questions above stress work 'for pay.' This excludes voluntary work and unpaid household work. In fact, data are available on both voluntary work (see Freeman, 1997) and household work (see Juster and Stafford, 1991), and the very same conceptual framework summarized below that is used to study paid work is also employed to understand these other types of work. However, this article concentrates on work for pay and, subsequently, whenever the word 'work' is used, it should be understood that 'work for pay' is meant. Most of the research by economists during recent decades has addressed the supply of labor to the labor market as a whole, not the supply of labor to particular occupations or to particular firms or industries. Research on labor supply to particular occupations or to particular firms uses models similar to the one sketched below to understand the supply of labor to the entire labor market, although there will necessarily be some differences in the analysis. For a review of some research on occupational labor supply, see Freeman (1986). For a study of the labor supply to a single firm, see Nelson (1973). In this article, the research reviewed concerns the supply of labor to the labor market as a whole.

Key Empirical Regularities

Any satisfactory theory of work behavior should explain the following empirical regularities:

1. Men work more than women.
2. In North America and Western Europe, white men work more than black men.
3. In recent years and in relatively rich economies, those who have been at school longer work more.
4. Unmarried men work less than married men while, until recently at least, married women work less than unmarried women.
5. Work hours and employment–population ratios fall in recessions and rise in booms though this procyclical movement is stronger for low-skill than high-skill workers.
6. Over the past century, in North America and Western Europe, for most types of workers, work hours have fallen and vacations have lengthened. A particularly instructive illustration of this for the USA is provided in **Figure 1**, which graphs the usual length of the workday by wage decile. The unbroken line in this graph draws upon information from various surveys in the 1890s, while the broken line provides information from a special Current Population Survey in 2004. The length of the workday has fallen for all workers except those at the highest wage decile. Indeed, whereas low-wage workers once worked the longest hours, high-wage workers now tend to do so. **Figure 1** describes US women, but the data for US men are similar (see Costa, unpublished papera).
7. Among men, work rises with age until middle age and then falls.
8. Although comparisons across countries are frustrated by differences in data collection methods and definitions, it appears that, in the 2000s, average hours worked in the USA exceeded those in most European countries.
9. Average hours worked by self-employed people tend to exceed those by employees (see Aronson, 1991).

No doubt, instances will be found where these patterns are contradicted, but these empirical findings constitute the norm. A rich literature exists in economics on these issues.

One empirical regularity has received much less attention, the fact that individuals synchronize their work schedules: slightly more than 80% of full-time workers in the USA start work between 6 and 9 a.m. while slightly less than 80% finish between 3 and 6 p.m. and these fractions have remained stable since the 1980s (Mellor, 1986); about 78% of all those employed do not work weekends, a number that has increased slightly since the 1980s (Smith, 1986). Presumably there are

Figure 1 Usual length workday by hourly wage percentile, women aged 18 to 64, 1890s and 2004.

strong complementarities in work and leisure activities (i.e., the benefits to one individual from engaging in a given activity are greater if other individuals also engage in that activity at the same time) although little research effort has been directed toward identifying the key complementarities. Weiss (1996) has been one of the few to grapple with this issue.

An Informal Statement

Classifying the Variables

In essence, economists think in terms of an individual's time spent at work as depending upon four classes of variables: (1) pay per unit time at work; (2) other income; (3) certain demographic characteristics that are observed by researchers; and (4) characteristics of the individual that are unobserved by researchers.

Consider these variables in turn. First, the dependent variable: time spent at work. There are many different dimensions of work time, including annual hours of work, annual weeks worked, weekly hours, daily hours, and whether to work or not.

Now the independent variables. 'Pay per unit time at work' is designed to measure the incentive to work or, equivalently, the price of not working. It is usually measured by an individual's average hourly earnings. Economists usually presume that posttax earnings matter, not pretax earnings. Where average hourly earnings do not vary with time at work, then the use of hourly earnings is appropriate to characterize the incentive to work for pay. However, there are a number of instances where the wage per hour is not fixed but varies (often increases) with work hours, so average hourly earnings may provide only a local indicator of work incentives. For instance, in many countries, by statute or by union-negotiated collective bargaining agreements, or by the operation of market forces, wage premiums are paid for long hours worked per week. Or job offers come in tied wage-hours packages: one employer may offer a job specifying a wage of US$10 per hour for 40 h per week while another may specify a wage of US$12 per hour for 42 h. In these instances, the incentive to work is not provided by a single wage rate that describes all work opportunities.

The variable 'other income' is sometimes represented by the individual's rent, dividends, and interest, so-called nonlabor income. This type of income for an individual is often the consequence of labor income earned at an earlier age and, therefore, will tend to be higher for those who habitually work long hours. In this way, high nonlabor income will tend to be a result of, rather than a cause of, long work hours. Hence, some researchers prefer to use some measure of wealth at a young age (if the data are available to measure it). Or 'other income' is sometimes represented by the labor income of other family members.

It is routine to examine the relationship between time at work and wages holding constant certain demographic characteristics, such as gender and race, characteristics that are typically included in surveys and that are available to researchers. Even allowing for differences in wages and other income, work patterns vary by race and gender, suggesting either systematic differences in 'tastes for work' or different work and nonwork opportunities for these groups.

Finally, it is recognized that much of the variation in work behavior across individuals remains unaccounted for after holding constant all the variables that are usually provided in large data sets. Expressed differently, variables unobserved by researchers 'explain' most of the variation in work across individuals. These unobservables are sometimes called 'tastes for work,' but it should be understood that this is simply giving a name to our ignorance.

The Nature of the Available Data

It is important in understanding any empirical labor supply research to recognize the essential source of variation in the data that is being exploited to measure the effects of various variables on work. One source of variation is across people: the correlation between work and other variables (especially wages and other income) is computed across people observed at approximately the same time. This correlation is often calculated separately for men and women and for different racial groups. A different source of variation is over time: here, in essence, the average values of each individual's work and other variables are first computed, then variations over time around each individual's average in work and other variables are calculated to form the relevant correlations.

Although it is straightforward to compute these correlations, they are sometimes difficult to interpret. Consider the effect of wages on work behavior, a subject that has been the focus of most of economists' research on labor supply. An ideal experiment from which to infer the effect of wages on work would be to select people in the population at random, assign wages to them prior to their work choices, and then observe whether and how much they work. In this experiment, the parts played by the random selection of the population and the prior assignment of wages to people are very important. Unfortunately, nature does not provide us with these ideal experimental conditions.

First, the wages that people face at any moment are determined in part by individuals' past decisions about how long to stay at school and what skills to acquire. These past schooling and training decisions may have been made with the expectation of capitalizing on them subsequently by working longer hours in the labor market. People who are less averse to market work are more likely to stay at school longer and to acquire the skills that result in relatively high wages later in life. In this event, the correlation between work hours and wage rates incorporates a causation that runs from preferences about work hours to wages rather than the other way around. Wages are not assigned to people in the manner described by our ideal experiment; in part, wage differences across people reflect people's prior decisions and their past and current preferences.

Second, when computing the correlation between work hours and wage rates, the wage rates facing people who choose not to work for pay are usually unobserved. Expressed differently, information on the wage offers that nonworkers are rejecting is not available to researchers. This problem is typically addressed by computing the hours–wage correlation among those working positive hours only. However, this generates the problem that the sample of people who choose to work does not represent a random sample of the population but a highly nonrandom and self-selected sample. The requirement of our ideal experiment that the correlation between work and wages be computed for people who constitute a random sample of the population is not met. This is one manifestation of what has become known as the problem of 'sample selection' and it has been emphasized in Heckman's influential research (e.g., Heckman, 1979). The sample selection problem arises whenever factors unobserved by the researcher affect both (1) the selection of the sample over which the hours–wage correlations are to be computed and (2) the hours of work decisions of the individuals. In this case, the ideal experimental condition – the random selection of the sample – is not being satisfied, and the meaning of the hours–wage correlation is subject to more than one interpretation (as shown succinctly by Heckman, 1993).

Therefore, the data available to researchers to compute the effect of wages and other variables on work behavior probably do not satisfy certain ideal experimental conditions, and this frustrates measuring the behavioral parameters governing the impact of these variables on work choices. However, the closer the variation across individuals or across time is to this ideal, the more reliable the resulting estimates are likely to be. For example, estimates from a study that utilizes variation both across individuals and across time, that resulted from policy changes that impacted some areas but not others, will be more reliable than a study that utilizes only cross-sectional variation in gross wages that resulted from individual schooling and occupation choices.

Conceptual Framework

Static Models of Labor Supply

To model an individual's work decision, let his or her preferences for work hours (h) and consumption (c) be embodied in a utility function $U = U(c, h; X, e)$, where X denotes fixed characteristics of the individual such as gender and race that are observed by researchers. Characteristics affecting preferences that are not observed by researchers are given by 'e'. The individual's income–expenditure constraint is expressed as $p \cdot c = w \cdot h + y$, where p is the price of consumer goods, y is nonlabor income, and w is average hourly earnings.

In the simplest and most tractable of cases, p, w, and y are fixed to the individual and independent of choices of c and h. In this instance, provided U has some convenient technical properties, selecting c and h to maximize U subject to the income–expenditure constraint yields an expression that relates hours worked, h, to the budget constraint variables that are given to the individual, namely, p, w, and y, and to the fixed characteristics conditioning his or her preferences, X and e: $h = f(p, w, y; X, e)$. This relationship is the labor supply function and it provides a formal justification for the characterization given in Section Conceptual Framework, whereby time spent at work is related to four classes of variables: w, y, X, and e. (Because the budget constraint may be written $c = (w/p) \cdot h + (y/p)$, it is evident that there are not three independent price and income variables, namely, p, w, and y, but only two such variables, namely, w/p and y/p.) As usual in economics, for the key empirical propositions, it is not essential that any individual behaves in this easily caricatured, maximizing manner, but that it facilitates the derivation of relationships and provides a convenient benchmark if we assume that the individual behaves as if he were deliberately optimizing. Less terse explanations of this model can be found in many good textbooks of Ehrenberg and Smith (2011) or Borjas (2012).

This framework applies to the individual who chooses to work a positive number of hours ($h > 0$) and to the individual who chooses not to work at all ($h = 0$). In the case of the decision of whether to work, the individual who is currently not working compares the wage per hour he would receive if he worked, the 'offered market wage,' with his reservation wage that is defined as the implicit value of his nonwork time. When his reservation wage exceeds his offered wage, he does not work for pay ($h = 0$); when his reservation wage falls short of his offered wage, he works some positive hours in the market ($h > 0$). Therefore, the higher is the offered wage, the greater the likelihood of an individual working for pay.

The previous statement concerns an individual's work decisions. Many people live in households where joint work decisions have to be made. In these cases, the standard treatment postulates a household utility function that depends upon the household's consumption and the work time of each household member. If incomes and expenditures are pooled, then each household member's work behavior will depend not

only on his wage rate but also on the wage rates of other household members.

This household formulation has been the subject of criticism for failing to specify how the household utility function is derived and for being silent on how resources are allocated within the household. In addition, many of the implications of this formulation tend to be rejected empirically (see Chiappori and Donni, 2009). Some recent models, then, start with the utility functions of individual household members each of which factor into the behavior of the household.

One version of these models characterizes household decision making as a bargaining process. Each individual has a level of welfare that can be enjoyed in the absence of cooperation with other members of the household. This is the individual's 'threat point' and is sometimes equated with the welfare the individual would enjoy if he or she left the household. Provided the household remains intact, anything that increases an individual's threat point will increase the individual's share of the benefits from remaining in the household. For instance, if the market wages paid to unmarried women rise, this increases the wife's threat point in bargaining with her husband and, provided the wife remains married, she should enjoy a greater share of resources within the household. This model has been used not only to understand husband–wife decision making and the growing incidence of divorce, but also intergenerational behavior in developing countries when adult children live with their parents. A formal treatment of these issues is found in McElroy (1990) and a more accessible discussion is in Lundberg and Pollak (1996).

Another version of these models does not take a stand on the form of the decision making process within the household, but postulates that the household reaches efficient decisions with respect to its consumption and work behavior. 'Efficiency' here means that, given prices and wages, the work and consumption decisions of the household members have exploited all opportunities to enhance their welfare without cost so that one person's welfare can be improved only by lowering another member's welfare (Chiappori, 1988). Recently, such models have been extended to account for labor force nonparticipation, nonlinear budget constraints, and discrete labor supply choices (Donni, 2003; Blundell et al., 1997).

Life Cycle Models of Labor Supply

When understanding work behavior over time, it becomes important to consider life cycle or dynamic models of labor supply.

In such models, there are two sources of variation in wages to which individuals may adjust their labor supply. The first is the life cycle variation in wages for a given individual; that is, the evolutionary changes in wages as a person ages. Typically, as an individual ages, their wages rise, sometimes at a decreasing rate, until later in life when wages begin to fall. The second source of variation in wages is the difference in wages across people at the same stage in their life cycle. This second source of variation in wages is called the parametric difference in wages across individuals. At any moment, differences in work behavior among people will be a mixture of responses of labor supply to, first, the path of wages as a given individual ages and, second, differences across individuals in wages observed at the same age.

The first of these responses may be observed if the work behavior and wages of a cohort of people born at about the same time are followed as they age. The proportional change in hours worked that follows a proportional change in wages as these individuals age is called the intertemporal substitution elasticity. It is the life cycle effect of wages on work.

The second of these responses may be observed by sorting individuals by age group and computing the correlation between work and wages across people within each age group. These people are about the same age, but they are born in different years (as they belong to different cohorts) so that the observations on their work and wages must be drawn from different calendar years. This correlation incorporates the response of labor supply to parametric differences in wages across people.

Labor Supply and Taxes

Because changes in income and payroll taxes, as well as changes in welfare benefits, are tantamount to changes in w (and sometimes in y, too), the impact of these tax and welfare policies depend on whether, and by, how much hours worked and employment–population ratios increase or decrease as w is altered. As a result, features of tax and transfer policies are often incorporated into labor supply models.

If t is the tax rate, w represents gross (that is, pretax) hourly earnings, and y is gross (pretax) nonlabor income, then net or posttax wages are defined as $w^n = (1-t) \cdot w$ and net or posttax nonlabor income is $y^n = (1-t) \cdot y$. If each individual responds to net wage rates and net nonlabor income, then the relevant budget constraint involves the posttax variables: $p \cdot c = w^n \cdot h + y^n$.

The problem posed for researchers measuring the effect of income taxes on labor supply is that, in most income tax systems, tax rates change with income (which, in turn, changes with work hours) so that the net wage rate varies as an individual alters his work hours. This means that the incentive to work is not represented by a value for hourly earnings that is fixed to the individual and independent of their work choice. Instead, there is no single value that represents the incentive to work because the net hourly wage at, say, 20 h of work per week will diverge from the net hourly wage at 40 h per week. In this instance, the budget constraint, $p \cdot c = w^n \cdot h + y^n$, is no longer linear.

It is not only the explicit income tax system that produces nonlinearities in the budget constraint. Most income-maintenance programs designed to provide support for low-income people also result in nonlinear budget constraints for individuals eligible for such programs. This is because most income-maintenance programs do not transfer a fixed sum that is independent of the recipient's income. On the contrary, most transfer programs are income conditioned: less money is transferred to the recipient as the recipient's income rises, until a point is reached, the so-called break-even point, where transfers are reduced to zero and the individual moves off the welfare program and is faced with just the (positive) income tax system. The rate by which transfer income is reduced as the welfare recipient earns one more dollar is the welfare system's

implicit tax rate. Virtually all implicit tax rates are very high, often as high as 100% when transfer income is reduced by one dollar for every dollar that the individual earns, so that budget constraints of low-income people are highly nonlinear.

Empirical Research

A large amount of empirical research has been directed toward the relationship between hours and wages.

In labor economics research in the 1970s and 1980s, the most common source of information to examine the relationship between hours worked and average hourly earnings consisted of large cross-sectional data sets; that is, data on individual people observed at approximately the same calendar time. In essence, after controlling for differences among people in many characteristics, the residual correlation was computed between time spent at work and average hourly earnings. In other words, the impact of wages on work was inferred from differences among people in their wages and work after controlling for other variables.

The most common finding in this research was that, among adult men, hours worked and wage rates were mildly negatively correlated; whereas, among adult women, hours worked and wage rates were positively correlated. A summary and evaluation of these studies appear in Killingsworth (1983), Pencavel (1986), and Killingsworth and Heckman (1986). However, the particular results were disturbingly fickle: relatively small changes in the composition of the sample or in estimating methods sometimes had large effects on the magnitude of the work–wage correlations. Mroz (1987) provides an excellent demonstration of this. Nevertheless, some recent papers that have employed similar methodologies (Blau and Kahn, 2007; Heim, 2007) have found that the correlation between hours and wages among married women has dropped substantially in the past two decades, suggesting that wages have less of an impact on hours among this group now than was the case in the 1970s and 1980s.

The first study to use data that followed people over time and estimate the two different types of labor supply responses in a life cyle model was MaCurdy (1981). His estimates of the intertemporal substitution elasticity for adult US men were in the order of 0.23, meaning that a 10% growth in wages as an individual ages would induce a 2.3% increase in annual hours worked. His estimates were imprecise, but more recent estimates for both men and women derive similar values for the intertemporal substitution elasticity (see Pencavel, 1998, unpublished paper).

When individuals are sorted by age and the correlation between work and wages computed across people holding age approximately constant, the subsequent estimate of the impact of wages on work is often (though not invariably) positive: for both US men and women, a representative estimated elasticity of annual hours with respect to wages is of the order of 0.10. (The elasticity of hours with respect to wages is defined as the proportional change in hours induced by a proportional increase in wages.)

Whereas in the research in the 1970s and 1980s it was common to compute negative estimates of labor supply elasticities, in the 1990s the estimates were more frequently positive and appeared less sensitive to modifications in specification and methods. Why should this be? First, there was a better understanding about the need to distinguish conceptually among different possible wage effects on work behavior. In particular, researchers differentiate the incentives for an individual to work at ages when his wages are relatively high (this is the life cycle effect) from the incentives to work that come from wage differences arising for reasons that are independent of age (this is the effect of parametric differences in wages). Second, the 1990s research had an important time series dimension, which may be a critical feature given that, over the past 20 years or so, the structure of wages has changed considerably. This generates a variation in wages that was denied to researchers in the 1970s and 1980s who relied exclusively on wage differences among people at a given moment.

Though there remains some disagreement among economists regarding the value of the elasticity of hours worked with respect to wages, it is undeniable that positive estimates of the effect of wages on work would help to explain many features of changes in work behavior over the past 25 years in the USA. Work levels have increased more for women than men, they have increased more for well-educated people than poorly educated people, and they have increased more for married people than for single people. In each of these three comparisons, the wage structure has changed favoring those who work more: the wages of women have risen relative to those of men, the wages of well-educated workers have risen relative to those with less education, and the wages of married people have risen relative to the wages of unmarried people. One simple story compatible with these facts is that changes in technology and other factors have caused changes in the wage structure and – if work–wage relationships are positive – these wage changes have induced relatively more work from those whose wages have risen relative to those whose wages have fallen.

Positive work–wage estimates may also explain some of the empirical regularities listed in Section An Informal Statement. Men work more than women and, other things equal, men are paid more per hour than women. White men work more than black men and, other things equal, white men are paid more than black men. Those with more schooling work more and have higher average hourly earnings. Unmarried men work less than married men, and unmarried men tend to have lower wages than married men. Unmarried women work more than married women, and unmarried women tend to have higher hourly pay than married women. The work–age patterns for men broadly correspond to their wage–age patterns. No doubt, there are other competing explanations for these regularities, but the naive positive association between work and wages across these groups is striking.

Other Empirical Findings

Labor Supply and Taxes

One aspect of empirical labor supply research that has occupied a large amount of attention is the impact of income taxation and transfer programs on work behavior.

Studies of this type done in the 1980s and 1990s often attempted to reproduce the essential features of individuals'

posttax and posttransfer budget constraints and explicitly estimate the parameters of the economic model. When the tax system can be characterized as generating a posttax budget constraint for an individual in which posttax wage rates are continually falling as more hours are worked (i.e., a budget constraint that is strictly concave from below as implied by a smoothly progressive tax system), the statistical procedures for estimating the effect of wages and taxes on work behavior are relatively straightforward and tractable (Hausman, 1981). When, however, the posttax budget constraint has kinks and net wages may rise over some regions as hours increase, the statistical methods become more complex and the results more sensitive to alternative estimation methods. Blundell and MaCurdy (1999) survey results from these studies. Though the wage effects estimated for married women are typically larger than those found for men, and though most studies find negative income effects, the variation in the estimates is striking. The essential source of the difficulty for researchers is that most data sets provide little information about the income tax and transfer programs that households face. Consequently, with the information available on gross wages and income, in effect, researchers try to complete the income tax and transfer algorithms for each individual, but the inaccuracies in this process and the errors introduced must be extensive. In addition, some of these methods implicitly constrain the estimates to imply positive wage effects and negative income effects (MaCurdy et al. (1990)).

A similar problem exists in trying to determine the impact of welfare or income maintenance programs on labor supply. A popular hypothesis is that some people reduce their work levels and, therefore, their market earnings to become eligible for welfare. This is revealed, it is argued, by the fact that welfare participation (the fraction of households receiving welfare payments) is higher in those states in the USA where the welfare program parameters imply relatively generous benefits. The problem with this argument is that, even in the absence of any work incentive effects of the welfare system, an association between welfare participation and the parameters of the welfare system are to be expected. Where welfare program parameters imply relatively generous welfare benefits, households will accept opportunities to raise their disposable income and participate in the welfare program, even if they do not change their work behavior. The association between welfare participation and welfare program parameters (especially the welfare system's implicit tax rate) has to be specified carefully to identify work incentive effects (see Ashenfelter, 1983). Unfortunately, because very few differences across states exist in the statutory implicit tax rate on welfare income, little persuasive evidence on the work disincentive effects can be gleaned from state to state variation in policies.

Much of the recent research on labor supply has been devoted to examining the impact of changes in particular program parameters on labor supply and labor force participation. A popular focus of study has been the Earned Income Tax Credit (EITC) (or a related credit in the UK, the Working Families Tax Credit) which provides a sizable tax credit for low-income working individuals. These studies typically use estimation strategies that compare a group impacted by the policy change (often single mothers) to a comparison group similarly situated but not affected by the change. A recent survey by Eissa and Hoynes (2006) notes that studies on the EITC generally find that labor force participation rates increase in response to an expansion of the credit, but that hours of work are largely unaffected.

Some researchers have moved away from examining the impact of posttax wages on hours of work, and instead attempt to measure the impact on tax rates on earned incomes. The rationale for this switch is that hours of work may be a poor measure of work effort for some individuals (such as executives and those working on commission) who have a large amount of discretion over their work activities. These studies (surveyed in Saez et al., 2012) also often compare individuals who were and were not impacted by a change in tax rates to identify the impact of the change, and typically find that earned incomes increase in response to a decrease in tax rates.

Family Labor Supply Decisions

The employment probabilities of husbands and wives do not appear to be independent of one another. To show this, consider households in the USA where both the husband and the wife are aged between 25 and 64 years. (The data are drawn from the 2012 March Current Population Survey, which asks questions about labor force behavior in 2011.) **Table 1** presents the joint and unconditional probabilities of market work of these husbands and wives. The probability that both the wife and the husband work is 0.633 and the probability that the wife works but the husband does not is 0.071. Hence, the sum of these two joint probabilities is the unconditional probability of the wife working which is 0.704 (given in the bottom line of **Table 1**). Similarly the probability that the wife does not work but the husband does is 0.242 and (as already noted) the probability that both the wife and the husband work is 0.633. Hence, the sum of these two joint probabilities yields the unconditional probability of the husband working which is 0.875 (given in the last column of **Table 1**).

Table 1 Joint and unconditional probabilities of employment of husbands and wives in the USA, 2011

		Probability of wife		
		Not working	*Working*	*Unconditional probability*
Probability of husband	Not working	0.054	0.071	0.125 (Probability of husband not working)
	Working	0.242	0.633	0.875 (Probability of husband working)
Unconditional probability		0.296 (Probability of wife not working)	0.704 (Probability of wife working)	

From these joint and unconditional probabilities can be derived the conditional probabilities and these are listed in Table 2. For instance, the probability that the wife works conditional on the husband working is 0.723, given in the first line of Table 2. Or, the probability that the husband works conditional on the wife also working is 0.899, given in the third line of Table 2. If both the husband and wife's employment probabilities were independent, then the conditional employment probabilities in Table 2 would equal the unconditional probabilities in the final column and the final line of Table 1. In fact, the conditional probabilities of the wife working are 0.723 and 0.568 (given in the first two lines of Table 2), whereas the unconditional probability of the wife working is 0.704 (from Table 1). The conditional probabilities of the husband working are 0.899 and 0.818 (given in the last two lines of Table 2) while the unconditional probability of the husband working is 0.875 (from Table 1). These data suggest that employment independence is closer to being satisfied for husbands than it is for wives. However, for both husbands and wives, the probability that one is employed is greater if his or her spouse is also employed. Consistent with this, working husbands and wives tend to retire at, or close to, the same time (see Hurd, 1990; Costa, unpublished paperb).

There are a number of reasons why employment probabilities of husbands and wives are positively correlated. First, this may reflect something about marital choices: women less averse to market work tend to marry men with similar work preferences. Second, the correlation may be that each party's responses to their shared economic environment. For instance, if both husbands and wives work more in households possessing little nonlabor income, then the positive correlation in work behavior may reflect the common influence of this source of wealth. Third, the correlation may be the outcome of both marriage patterns and economic environments. For example, it has already been reported that those men facing higher wages are more likely to work in the market than lower wage men and those women facing higher wages are more likely to work in the market than lower wage women (1). Furthermore, high-wage men tend to marry high-wage women (2). Together (1) and (2) will generate a positive correlation between the employment probabilities of husbands and wives.

The positive correlation in the market work of husbands and wives may also reflect cross-wage effects. That is, hold the wages of the husband constant: then, do those husbands married to relatively high-wage wives work more than those husbands married to relatively low-wage wives? Conversely, hold the wages of the wife constant: do those wives married to relatively high-wage husbands work more than those wives married to relatively low-wage husbands? This issue has arisen in the last few decades as a possible reason for the growth in the employment–population ratio of married women. A popular explanation has focused on the slow growth in the wages of married men since the early 1970s: are married women working more because the wages of their husbands have increased so little or, in some instances, have actually decreased? The broad trends in the key variables support such an interpretation because there has been a steady increase in the market work of married women while, for the past 25 years or so, median real wages of married men have increased hardly at all.

Indeed, the work decisions of husbands and wives do seem to be related to the wages of their spouses. In particular, when one spouse's real pay falls, the other spouse tends to work more (see Juhn and Murphy, 1997; Pencavel, 1998, unpublished paper; Heim, 2009). However, these cross-wage effects – the relation between one individual's work behavior and his or her spouse's real earnings – are much less powerful than the own-wage effects – the relation between each individual's work behavior and his or her own real wages. According to these findings, the employment of married women has increased principally because their real offered wages have been increasing and the movements of their husband's earnings have been a factor, but a factor of less importance in accounting for the movements in their work levels.

If women were working more to augment the stagnant pay of their husbands, then the increases in the work of married women should be greatest for those men whose wages have fallen, not for those men whose wages have risen. In fact, the largest increases in work among women have occurred for those women married to high-wage men and the real earnings of high-wage men have tended to increase in real terms since the 1970s. By contrast, the market work of wives of low-wage men has increased much less and yet the real wages of low-wage men have tended to fall. These facts are reported in Juhn and Murphy, (1997).

Hence this evidence suggests that husbands and wives tend to substitute their work time for one another: when the wage rate of one party increases (decreases), that person works more (less) and his wife or her husband works less (more). The positive correlation in the employment probabilities of husbands and wives is driven more by marriage patterns and by own-wage effects than by cross-wage effects.

Table 2 Conditional probabilities of employment of husbands and wives in the USA, 2011

Probability of wife working conditional on husband working	=Probability of both husband and wife working divided by the unconditional probability of husband working	=0.633/0.875	=0.723
Probability of wife working conditional on husband not working	=Probability of wife working and husband not working divided by the unconditional probability of husband not working	=0.071/0.125	=0.568
Probability of husband working conditional on wife working	=Probability of both husband and wife working divided by the unconditional probability of wife working	=0.633/0.704	=0.899
Probability of husband working conditional on wife not working	=Probability of husband working and wife not working divided by the unconditional probability of wife not working	=0.242/0.296	=0.818

Work Behavior of Older People

One of the most striking of long-term developments in work behavior is the decline in employment of older men. Of men 65 years and older, 68% were in the labor force in 1890, 42% in 1940, 31% in 1960, and fewer than 20% in the mid-1980s. Interestingly, from the mid-1980s to 2010, this decline appears to have flattened out or reversed slightly (Kromer and Howard, 2013). Similar declines in hours of work among those men employed are also observed. By contrast, the labor force participation rate of women aged 65 years and over has changed relatively little: it was 8% in 1890, 8–10% in the 1980s and 1990s, and 12.5% in 2010.

The drop in the amount of work allocated by older men to the market is one definition of retirement. Another definition, often accompanying the first, turns on the receipt of pension or social security income. It is tempting to convert this association into a causal relationship: retirement in the sense of the reduction in labor supply among older workers is induced by the opportunity to draw on annuities from accumulated pension funds.

Because the dominant retirement income for the median elderly household is social security income, a much researched issue has been the impact of social security on retirement. For most of the past 50 years or so, social security wealth has been increasing over time while male labor force participation rates have been falling so the aggregate time series movements in these variables are compatible with a causal role for public pensions. However, monthly income from social security was first paid in 1940 to a relatively small fraction of the elderly population at which time labor force participation rates of men of 65 years and over had already fallen by more than 20% since the beginning of the century. As Costa has noted (1998: pp. 20–21), in the USA and other countries (Britain, Germany, and France), retirement trends do not display a discontinuity around years when, as a consequence of new legislation, public pension benefits start being paid.

However, a role for social security affecting retirement behavior is suggested from an examination of the retirement patterns of the members of a given cohort as they age. In particular, since the mid-1960s when early social security benefits were first introduced, there has been a spike in male labor force participation rates at age 62 years. It is difficult to understand why there should be such a spike at 62 years other than the discontinuous retirement incentives embodied in the Social Security benefit rules.

In addition, certain private pension programs create incentives to retire before the age of 65 years. Defined-benefit pension plans specify the pension annuity as a fixed proportion of a worker's highest annual earnings and often the actuarial value of such defined-benefit plans is higher for people younger than 65. In contrast, defined-contribution plans embody no incentives for early retirement, since pension wealth grows until the funds are withdrawn. Because the fraction of workers covered by defined-benefit pension programs has been falling and that of defined-contribution pension plans increasing, the prevalence of early retirement incentives in private pension programs has been on the decline.

Nevertheless, the growth in social security and in private pensions represent specific manifestations of a more general phenomenon; namely, the increase in wealth that many cohorts have enjoyed this century. This increase in wealth discourages market work at some time during an individual's life and it may be efficient for the typical individual to take this increased leisure not in the form of fewer work hours each year, but in the form of fewer years at work and of earlier retirement.

Differences in Work–Wage Elasticities

In undergraduate textbooks, for many years it has been common to draw graphs of the relationship between hours worked and wages that imply a positive association at relatively low wages and a negative association at relatively high wages. This nonlinear relationship is called a 'backward bending labor supply curve.' Although this curve is a staple of every economics student's education, the empirical support for this relationship is meager. In some instances, researchers have specified the relationships in such a way that a nonlinear and nonmonotonic relationship between wages and work hours was not investigated. In other instances, however, researchers have explored the possibility of this backward-bending curve and found little evidence for it.

With the richer and more recent data, the issue has come up for re-examination. It surfaced because the impact of wages on work appeared to be larger for men with relatively low levels of schooling than for well-educated men, and it was a short step to move from this observation to a specification in which the impact of wages on labor supply fell as wages rose. Indeed, according to one set of estimates, the elasticity of annual hours worked with respect to wages is calculated to be of the order of 0.33 at the average wage of men with less than a high school education, and it falls to 0.14 at the average wage of men with more than 16 years of schooling (see Pencavel, unpublished paper). Note, however, that although the slope of the hours–wage relationship becomes less positive at higher wages, it never becomes negative, except for a very few people with extremely high wages. A similar result is obtained by Juhn and Murphy (1997), though Kapteyn et al. (1990) and Bloemen (2009) find evidence of a backward bending labor supply function for larger fractions of married men.

Conclusion

Over the past 50 years or so, there has been a very large volume of research on labor supply by economists. This is because the work decisions of individuals represent one of the essential components of labor market analysis (in the classical metaphor, these labor supply decisions represent 'one blade of the scissors,' the other blade being the hiring and employment decisions of firms) and because questions involving labor supply are closely tied to important issues of the public policy (such as the effect of income taxes on how much individuals work). This research has been increasingly sophisticated in economic and statistical modeling. In addition, much more is known today about work patterns than was known in 1960. Some components of the economist's standard model of labor supply (such as the intertemporal substitution elasticity), and the labor force participation impacts of some policies (such as the EITC) have been estimated with confidence. However, there remains some disagreement over the values of other key

parameters such as the effect across different individuals of increases in wages on hours worked. Most economists probably believe that, for the typical worker, increases in wages generally induce relatively small increases in work hours although researchers would refrain from confident statements about precise magnitudes.

Abstract

Labor unions are interest associations of workers in waged employment. The article summarizes their treatment in the social sciences and describes their rise in the industrial and political history of Western societies. It outlines the main dimensions of union organization and union growth and summarizes the literature on modern unions as collective actors in their three principal arenas: the labor market, the workplace, and the polity. The article concludes with a discussion of the prospects of unionism today.

Labor unions are interest associations of workers in waged employment. They are formed to improve the market situation and the life chances of their members, by representing them in the labor market, at the workplace, and in the polity, and in particular by collectively regulating their members' terms of employment. Unions emerged in the transition to industrial society in the nineteenth century, together with the defeudalization of work, the rise of free labor markets, and the commodification of labor. While employing modern means of formal organization, they represent an element of traditional collectivism in a market economy and society. Unions have taken a wide variety of forms and adopted different strategies in different historical periods, countries, and sectors. They are therefore favorite subjects of comparative social science.

Unions in the Social Sciences

The literature on unions is vast and extends into several disciplines. In the Marxist and socialist tradition, authors in the late nineteenth and early twentieth centuries debated whether and how unionism might contribute to the overthrow of capitalism or, to the contrary, its stabilization. Democratic reformers like Beatrice and Sidney Webb explored the potential contribution of unionism to the governance of a democratic industrial society. Institutional economists, such as Commons and Perlman in the United States or Brentano in Germany, tried to understand the economic causes and consequences of unionization. Neoclassical economists like Böhm-Bawerk explored the capacity of unions to override market prices and achieve a lasting redistribution of resources, while their successors in the 1960s applied theories of monopolistic competition to analyze the impact of collective bargaining on wages (Chamberlain). Early econometric analyses studied the impact of economic fluctuations on union organization and union activities, including strikes (Ashenfelter). The discipline of industrial relations, which grew after World War II in the US (Dunlop, 1993) and Britain (Flanders, Clegg), focused on unions as participants in collective bargaining under the 'New Deal' and in the postwar 'mixed economy.' Sociologists took an early interest in the transformation of unions into centralized and bureaucratic mass organizations with a staff of full-time officials (Cassau). Postwar American research on union democracy was in particular interested in the sources of communist influence in unions, while macro-sociological studies have investigated the origins of unionism in the context of social protest movements and their integration in the modern nation-state (Tilly). Political sociology and political science display a lasting interest in the role of unions in the polities of industrialized democracies. Economists study the economic effects of unions, in particular with respect to relative factor prices, inflation, productivity, and employment (Freeman and Medoff, Calmfors and Driffill, Soskice). Similar concerns figured prominently in historical institutionalist research and theory on neocorporatism in the political economy of advanced European welfare states (Schmitter, Crouch). Labor law has long been concerned with the rights of unions vis-à-vis employers, and with reconciling collective bargaining and collective industrial agreements with civil law and the freedom of trade and contract. Constitutional lawyers, in particular on the European continent, have tried to clarify the status of unions and collective bargaining in relation to the state and public legislation.

The Rise of Unionism in Industrial Countries

Unions emerged in conflict with both economic liberalism and political authoritarianism, striving simultaneously for economic regulation and political freedom. As a result, they were originally treated as conspiracies against free trade, the state, or both. But as unions established themselves as effective labor market cartels, they also became suppliers of labor to those employers willing to deal with them, and in this capacity slowly turned into 'managers of industrial discontent' (Flanders). Similarly, while unions represented the interests of a class opposed to the advance of capitalism, their toleration in the course of democratization contributed to the transformation of liberal into organized capitalism, and was central to the institutionalization of compromise between capital and labor. The integration of unionism and working class collectivism in the institutional framework of modern industrial societies turned unions into legitimate intermediary organizations between their members on the one hand and employers and the state on the other, and transformed class conflict into joint regulation of work and employment. It represents the foremost example of the stabilization of the capitalist economy through democratic politics and institution building.

Early unions saw themselves as democratic organizations of self-help and self-government of workers independent of the feudal or bourgeois predemocratic state. Often they belonged to broader labor movements that included political parties, consumer cooperatives, mutual assistance funds, educational associations, sports clubs, etc. While unions generally resented interference of the state and the law in their internal organization and activities, they differed widely in structure and ideology. Thus, syndicalist and anarcho-syndicalist unions, which in a number of countries remained significant well into the twentieth century, regarded themselves as constituent units of a direct democracy of producers set to replace both capitalist employers and the bureaucratic apparatus of the modern state. These traditions, which equally opposed capitalism and parliamentary democracy and favored direct action over both collective bargaining and political-electoral lobbying, culminated in the militant council movements of World War I and the revolutions following it, especially in the Soviet Union.

Integration of unions in democratic capitalism, and union recognition by governments and employers, was greatly advanced by the two World Wars. Economic mobilization and the governance of the war economy required the collaboration of union leaders, who in many countries came to be co-opted into positions of quasi-public authority. Also, enlisted soldiers had to be promised a better life in a fairer society upon their return from the battlefields, and in defeated countries traditional elites were replaced in the aftermath of war by liberal or socialist governments. Generally, the end of World War I brought political democratization and, precipitated by the threat of socialist revolution, widespread acceptance of collective bargaining. But the first postwar settlement proved fragile in countries like Germany, Japan, Italy, and Spain, where unionism was soon suppressed by authoritarian regimes and replaced with state-controlled mass organizations of workers that were put in charge of administering state social policy. Similarly, in the Soviet Union, workers councils were incorporated in a repressive state machinery and unions turned into 'transmission belts' from the state to the working class. In the United States, by comparison, the New Deal extended union organizing rights while the Swedish Social Democratic government of the 1930s and the British war cabinet of the 1940s began to develop the contours of the labor-inclusive Keynesian welfare state of the second postwar settlement after 1945.

The 'golden age' of capitalism in the second half of the twentieth century saw the worldwide ascendance of a 'mature' type of unionism, centralized at the level of the national state and pursuing economic and social policy goals through collective bargaining and political-electoral lobbying within the confines of capitalism and parliamentary democracy. This development was part of the consolidation of both democratic capitalism and the nation-state in the countries under American hegemony, where legal recognition of unions and free collective bargaining, extensive social welfare provision, a sizable public sector, and politically guaranteed full employment made possible the coexistence of liberal democracy and the market economy. The normalization of unionism under postwar 'embedded liberalism' (Ruggie) coincided with national regulation and standardization of the employment relationship and of the status of wage earners as distinguished from employers and the self-employed, which in turn corresponded to the advance of industrial mass production. Far-reaching legal and political regulation of the labor market, introduced to insulate employment and employment conditions as much as possible from economic fluctuations, stabilized union power. The worldwide outburst of labor militancy in the late 1960s, which took national union leaders by surprise, further added to union power, as governments, still feeling politically constrained to provide for full employment, more than ever depended on union cooperation for restoring economic and political stability.

Economic, political, and social change in the 1980s and 1990s caused a roll-back of unionism in most countries. In the 1980s, the British government proved that elections could be won even with high levels of unemployment. Under the leadership of the post-New Deal United States, governments also found less politically and economically costly ways to combat inflation compared to 'social contracts' with union leaders who had often turned out unable to deliver on their promises of wage moderation. Low inflation and high unemployment coincided with deep industrial restructuring, in response to economic internationalization and a new wave of technological change. Gradually this undermined the Fordist organization of work and the normalized employment relationship that unions had helped shape and with which they had learned to live comfortably. Also, the breakdown of Communism in the late 1980s eliminated the systemic opposition to capitalism that had made Western governments willing to make concessions to unions after the two World Wars. While private sector unionism has almost disappeared in the world's leading economy, the United States, it is, however, still firmly entrenched in many European countries, due to strong institutional supports left over from the social compact of the postwar era (Baccaro and Howell, 2011).

Union Organization and Union Growth

The first unions were local protest movements of the 'working poor.' In the mid-nineteenth century, they were superseded by formally organized craft unions of skilled workers which thrived particularly in the liberal political environment of early industrializing Britain and America. Commanding considerable market power, craft unions represented their members mainly through economic action. In addition to maintaining sizable mutual assistance funds, many of them were cartels that unilaterally fixed the price of their members' services. From the state, craft unions did not expect much apart from freedom of organization. While politically liberal, they were socially exclusive. Not only was membership in them reserved to the skilled. To control the labor supply, draft unions also limited apprenticeship training, prevented employers from hiring nonunion members for craft jobs ('pre-entry closed shop' for specific 'job territories') and defended an organization of work that ensured demand for their members' skills (job control unionism).

Where craft unions became firmly established, they survived beyond the second wave of unionization at the end of the century, when the growing masses of unskilled factory workers began to get organized. Given the weak market position of their

members, the 'general' unions that undertook to organize the large factories of the beginning age of mass production had to place their hope on the strength of large numbers. They therefore tried to recruit as many members as possible regardless of skill, although where craft unionism was strong, they mostly remained unions of the unskilled. While craft unions preferred a 'voluntarist' mode of operation keeping the state at arm's length, the new general unions emphasized political action and pressed for social legislation and state intervention in the economy.

In Anglo-America, where industrialization and democracy had come early, craft and general unions coexisted well into the twentieth century, with the former deeply influencing the practices and ideologies of the latter. By comparison, in late industrializing countries with authoritarian governments and narrowly limited political and economic opportunities for a market pursuit of collective interests, craft unions were mostly absorbed in inclusive 'industrial unions' organized by economic sectors. As these had originated in often-bitter political struggles especially for universal suffrage, their unionism was embedded in universalistic concepts of social and political reform that differed profoundly from craft particularism or American 'business unionism.' Frequently the new unions were allied to political parties, especially socialist and Catholic, and while craft unions had been fragmented by skill, industrial unionism was often fragmented by political orientation. Indeed as authoritarian governments had initially denied them the opportunity to represent their members economically, some of the new unions remained for long subordinate to political parties.

Craft unions, while narrowly based and normally small, were highly centralized where their members faced national labor markets. With the rise of the nation-state industrial unions, representing their members through political action for organizational rights, favorable labor laws, and social welfare legislation, also developed nationally centralized structures. In principle, these were usable for centralized collective bargaining as well, in solidaristic egalitarian pursuit of nationally standardized wages and employment conditions. However, getting members to support common demands in spite of often widely different situations at their workplaces required strong organizations. While political ideology helped, the capacity of national unions to aggregate the interests of a diverse membership depended in large part on whether employers were supportive of negotiation at national level. In countries with an established craft legacys, bargaining remained mostly decentralized and fragmented as industrial unions had to allow their members independent pursuit of sectional interests, on the model of and in competition with skilled unions. Sometimes, especially in the United States, unskilled unions managed to establish rights to 'job property' for their members as well and enforced on employers their own version of a closed shop, under which new hires had to join the union within a short period or lose their job (post-entry closed shop).

Union organizational development in the nineteenth and twentieth centuries included the rise of national federations of local and sectoral unions, which occurred in close correspondence with the formation of the modern nation-state and the establishment of liberal democracy. It also involved the growing independence of unions, not just from governments but also from friendly political parties, enabling even the industrial unions of the European continent to deal with democratically elected governments of conservative political complexion. Related to this was the increasing reliance of unions on collective bargaining with employers as their main mode of operation, with either individual firms or employers, associations. This presupposed the elimination of 'yellow' company unions controlled by employers as well as recognition of collective bargaining in labor law, for both of which government support was crucial. Collective bargaining, in turn, required that unions established organizational authority over strikes – the collective withdrawal of the labor power of workers from employers – just as political recognition of unions demanded that strikes were called only for economic purposes, abandoning the syndicalist tradition of the 'general' political strike. Union organizational development further involved integrating the growing number of white-collar workers, either into separate unions or inside encompassing industrial unions, which followed different trajectories in different countries and generally remained much less successful than the organization of blue-collar industrial workforces.

The literature offers a variety of explanations for the growth and decline of union membership over time and the differences in union density rates between sectors and countries. Unions tend to be strong in the core sectors of export-oriented manufacturing, like metal engineering, in large establishments, and in the public sector, while they are weak in private services and in small firms. But cross-country differences are considerable, and indeed on hardly any parameter of social structure do developed industrial societies differ as much. While in some Scandinavian countries around 80% of wage earners are union members, in France and the US density had fallen to about 10% by the end of the twentieth century. And while union membership relative to the workforce declined during the 1980s in the United Kingdom and the Netherlands, it increased in Belgium and Finland. Fluctuations in membership over time can also be enormous, as they were in Britain where in the 3 years between 1920 and 1923, union density declined from 45% to 30%.

Econometric studies have found that in the United States and Britain in particular, union density tended to increase with nominal wages and inflation, while it was negatively affected by unemployment and an already high level of unionization (Bain and Elsheikh). However, studies of this sort cannot explain the variation in unionization between countries, or ruptures in historical continuity. Institutionalist approaches take into account that union growth includes the acquisition by unions of recognized status, based on agreements with employers or the state helping unions recruit members ('union security'). Often such status is gained in exchange for political and economic moderation. Differences in union density then reflect different opportunities for unions to organize and keep members ('workers do not organize unions; unions organize workers'). In addition to the closed shop in its many official and unofficial versions – which makes membership compulsory by making access to employment dependent on it – employers may assist unions in collecting their membership subscriptions. Similarly, favorable legislation on union recognition or workplace representation through works councils may improve unions' ability to recruit. In some countries, like

Switzerland, nonmembers are legally obliged to pay union dues, and in Belgium and Denmark unions administer parts of the public social insurance system, enabling them to discriminate against nonmembers and thereby create additional incentives to join.

More generally, the organizing problems of unions may be described in terms of generic problems of collective action in the rational pursuit of group interests. Union achievements, like higher wages or favorable social policy legislation, are often collective goods in that they cannot be withheld from workers who have not contributed to their production. Apart from sentiments of fraternal solidarity, there is then little incentive for workers to join a union, even if they find the outcomes of union activities desirable. Indeed, given the risk that others will 'free-ride,' members may contribute in vain, as the union may not find enough support to be successful. Like other collective organizations, unions therefore typically offer potential members 'outside inducements' (Olson), i.e., benefits other than the collective goods for which they were originally founded, which unlike these can be limited to members (for example, health care benefits). They also strive to make membership less voluntary and obligatory, often with the help of the state or the employers.

Unions as Collective Actors

As intermediary organizations, modern unions represent their members in the labor market, the workplace, and the polity. Depending on their membership, their organizational structures and traditions, and the constraints and opportunities offered by employers and the state, different unions attach different significances to the three arenas and coordinate their activities in them differently.

Unions in the Labor Market

Unionism, and indeed much of modern labor law, assumes that individual workers are at a disadvantage vis-à-vis employers, and that redress of this imbalance requires that workers combine to face their employer as a collectivity. By regularizing wages and conditions of employment, sometimes also through state legislation, unions try to take wages and conditions out of competition, to make the market more predictable and protect workers' living conditions from its fluctuations. In this sense, Polanyi regards unionism as an element of the social countermovement against the 'satanic mill' of the 'self-regulating market' of early liberalism.

Economists have long debated whether unions can raise wages above the market level. Clearly, they can get nominal wage increases that exceed the increase in productivity, which depending on the government's monetary policy may result in either inflation or unemployment. With respect to the wage structure, in fragmented union systems skilled unions may use their independence to defend wage differentials, causing a wide wage spread between skill groups and industries. Fragmented ('competitive') bargaining may also enable well-organized groups of strategically placed unskilled workers to make high relative wage gains, which in turn may result in a 'leapfrogging' pattern of general, and potentially inflationary, wage increases. Wage differentials are also high in economies in which unions have little or no influence.

By comparison, industrial or general unions typically entertain an egalitarian ideology and strive to compress wage differentials, raising the wages of their less well-paid members more than those of the others. The result tends to be increased capital intensity and unemployment at the lower end of the labor market. Industrial unions therefore favor extensive training and retraining, funded by employers or the state, to increase the productivity of the less skilled to a level where they can earn the high wages negotiated for them. In favorable circumstances, this may lead to a general upgrading of a country or sector's production system, in the direction of more skill-intensive and less price-competitive production.

Since the 1970s, there has been a debate on the relationship between centralization of collective bargaining and various dimensions of macro-economic performance, such as inflation, growth, and employment. In the 1970s, centralized bargaining by national or industrial unions was believed by many to be more economically beneficial than fragmented bargaining, as it made it more difficult for bargainers to disregard the costs of redistributive bargaining or productivity-restraining work rules. Later it was suggested that bargaining agents in a decentralized wage setting system were more likely to be disciplined by market pressures, the problem being intermediate levels of centralization and unions, both large enough to override the market and small enough to be able to externalize the costs of their behavior to society. Statistical analyses have remained inconclusive and suggest that the economic effects of bargaining structures are highly conditional on economic and institutional circumstances.

Unions in the Workplace

Comparative research suggests that employers are willing to agree to centralized bargaining if this helps them keep unions out of the workplace. Workplace unionism, especially in a craft tradition, detracts from managerial prerogative and may interfere with management attempts to increase productivity. On the other hand, even industrial unions need to be present in the workplace, if only to recruit members, monitor the implementation of collective agreements, and generally insert themselves in the governance of the employment relationship and the 'wage–effort bargain' inherent in the labor process. Balancing central and workplace representation, or external and internal union organization, was and is one of the main problems of unionism and industrial relations.

Least of all, employers seem to like multiunionism in the workplace. This has often led to agreement with industrial unions on unified arrangements for plant-level workforce representation, like in Italy. In some countries, like the US, single-union representation is established by a legal procedure. In others, workplace unionism is merged into institutions of legally based participation, giving works councils elected by the workforce as a whole rights to information, consultation, and codecision-making while ensuring that management has a single counterpart with which to negotiate. While works councils in most countries cannot call strikes, they tend to have close relations with internal and external unions, not the least since most of their members are usually also union members.

In a number of Asian countries, unions have evolved into 'enterprise unions' that are only loosely federated above the enterprise level. This corresponds to an environment of closed internal labor markets and lifetime employment of core workforces. Enterprise unions tend to be highly cooperative with managerial efforts to increase productivity and competitiveness as they represent the close community of fate between their members and the enterprise that employs them. Often their officials are managers whose career is advanced by serving for a time in a union position. Works councils in European countries also tend to cooperate with management. Unlike enterprise unions, however, they exist next to an external union that can call strikes without regard to the competitive position of individual workplaces.

The economic effects of different forms of workplace unionism are still being debated. For some time, decentralized unionism and workplace bargaining were associated with high strike rates whereas centralized and politically influential unions, like those in Scandinavia, were found to be highly effective without much recourse to strikes. Especially where distributive wage bargaining is moved to the national or the industrial level, or where distributive conflict is suspended by jointly faced competitive market pressures, workplace representation was shown to enhance efficiency, among other things by enabling workers to voice complaints as an alternative to quitting. The same effect has been attributed to works councils. By comparison, in countries with adversarial industrial relation traditions, external labor markets, decentralized wage bargaining, freedom of workplace unions to call strikes, and a history of craft unionism and restrictive practices, workplace unionism came to be regarded in the 1960s and 1970s as a source of inefficiency. Here employers began to devise their own structures of workplace cooperation and 'worker involvement,' in the context of the developing practice of 'human resource management,' which often but not necessarily presupposes or aims at a 'union-free environment.'

Unions in the Polity

In most European countries, the rise of unionism was closely intertwined with nation-building and state formation. T.H. Marshall regards unionism as a step in the evolution from civil, to political, to social rights of citizenship, with unions using political rights to collective organization in the pursuit of social rights, albeit in the civil sphere of the marketplace and through freely negotiated – collective – contracts ('industrial citizenship'). As early repression of unions gave way to inclusion in shared public spaces (Crouch), unions became firmly integrated in the social and political order of the Western European nation-state, especially under the second postwar settlement after 1945.

The high point of union inclusion in advanced industrial countries was the 'neocorporatist' period of the 1970s and early 1980s. Especially in countries with a tradition of political unionism and centralized collective bargaining, unions were able to get major concessions from governments and employers in 'political exchange' for wage restraint, which in turn was to enable governments to protect full employment with Keynesian means without having to accept excessive rates of inflation ('incomes policies'). Among the concessions gained by unions in this period were legislation on union recognition and access to the workplace; various other forms of 'union security'; legal extension of collective agreements to all firms in an industry; higher social security and public pension benefits; and industrial democracy legislation. Neocorporatism was more likely to work where governments were of a social democratic complexion; but most conservative governments were also eager not to antagonize the unions. The more politically powerful unions became under corporatist arrangements, the lower as a rule was the strike rate as strong unions were able to get in the political arena what others had to struggle for, with uncertain event, in the industrial arena.

The historically close involvement of union movements with their respective nation-states explains to a large extent why unions and collective bargaining have so far resisted economic pressures for institutional convergence. In fact, the structure of unionism and its status inside its institutional context are an important dimension distinguishing between the different 'models of capitalism' that have attracted attention in the 1990s. The lasting symbiosis between union movements and national states also accounts in large parts for the weakness of international unionism. Such weakness is found even in the European Union, where in spite of deep economic integration national unions have remained highly distinctive in their organizational structures and *modus operandi*, and are jealously guarding their independence.

The Prospects of Unionism Today

Much of the literature on unions in the early 1960s observed and predicted a decline of unionism in leading industrial societies. In most Western countries, with the notable exception of the United States where union decline continued unabated, this was contradicted by the 'hot autumns' of 1968 and 1969, which were followed by a sharp reversal of membership losses and by unprecedented influence of unions in politics. In the 1990s, however, union membership and power were again declining worldwide. With the American private economy on the way to effective deunionization, the British government in the 1980s attacked unions' legal and institutional supports, with considerable success (Davis, 2009). Outside the Anglo-American world, union influence was weakened by the end of politically guaranteed full employment combined with intensified international competition, while the growing importance of the service sector and the 'knowledge economy' and the rise of a more diverse and better educated workforce made it more difficult for unions to recruit new members. Even where institutional conditions remained unchanged, unionism tended to be increasingly confined to the traditional sectors of the economy, which have long been shrinking in size and importance (Streeck, 2005).

In their history unions have become deeply involved in the functional and social integration of the modern nation-state: in the national standardization of employment practices, the organization of redistributive solidarity at national level, and the political governance of the national economy. The decay

of the second postwar settlement coincides with strong market pressures for more flexible modes of governance, less political interference, and internationalization of economic transactions. It is not clear whether and how unions, and indeed the nation-state itself, will find a response to the denationalization of the global economy. With their membership aging, unions may become defenders of an industrial employment and social security regime that no longer fits the needs of the rising postindustrial sector of the workforce. Being unattractive to the winners of structural change in the highly skilled and female segments of the labor force, unions also seem less than successful in organizing the new underclass of low-paid service workers, many of them immigrants, that has been growing for some time in many industrial societies.

Abstract

The main purpose of laboratory studies has long been taken as epistemological. Seen as the *coup-de-grace* for constructivist philosophy of science, early practitioners of laboratory studies were seen to have disproved demarcationist theories of scientific fact production. They were supposed to have done so by revealing the messy, intertwined, socio-technical world inside the laboratory itself. Because laboratory studies were seen in this way, they initially garnered sensational attention, but later were seen to be less important since the epistemological project was considered either to have been completed or to be a methodological non sequitur. This view of laboratory studies has obscured their actual importance and their continuing contributions to studies of science and technology. If laboratory studies are seen not as epistemological projects, but rather as investigations into technoscientific agency, their real and sustained importance to science and technology studies (STS) emerges. In this view, it can be seen that early laboratory studies set the stage for, and subsequent studies fleshed out and further challenged, debates regarding material agency, distributed organizational agency, and cultural agency in technoscience; debates that animate the field of STS to this day.

The idea of exploring scientific laboratories in real time as a means of understanding the nature of science began in the late 1970s with several ethnographies of laboratories in the USA. Since then, laboratory studies have played a founding role in science and technology studies (STS) and influenced a spectrum of established fields in the humanities from history to literary criticism. First, laboratory studies were a driving force in the rise of the Sociology of Scientific Knowledge (SSK), a movement that asserted on philosophical grounds that scientific knowledge was sociological. Laboratory studies were enrolled in, and sometimes enthusiastically enrolled themselves in, proving the manufactured nature of scientific fact-making at the 'actual site of scientific action' – the laboratory floor (Knorr Cetina, 1983: 117). This movement garnered a lot of attention, disrupting relationships between sociology, anthropology, history, and philosophy of science, instigating new approaches in the humanities, and challenging the relationship between the sociology of science and science itself – culminating in the 'science wars' of the 1990s. Since that time, however, after all the sensational sturm und drang, the epistemological project in laboratory studies has quietly died down, and, depending on the author, the goal of proving that scientific knowledge is sociological is seen as either complete, failed, or a methodological non sequitur. As a result, the kind of programmatic attention afforded to the initial laboratory studies has not been as prominent in subsequent studies of laboratory science. Regardless of this lack of wider attention, however, laboratory studies continue to make up a rich field of inquiry that has built in important ways upon the instigations effected by the initial studies. In order to see this importance, however, one must not look at laboratory studies as epistemological projects, as they were initially and sensationally held to be. Rather, they should be viewed as investigations into technoscientific agency. Indeed, if one casts such an eye back over the history of laboratory studies, it can be seen that their real importance was missed the first time around, and their actual contributions have run beneath the radar ever since. If laboratory studies are looked at through a lens of agency, rather than considered for their self-proclaimed or attributed contributions to epistemology, they can be seen as important precursors and developers of influential concepts regarding human and technological actions, which have been taken up in the broader field of STS. Far from being micro-sociological studies, the early laboratory studies developed sophisticated conceptions of agency that spurred conceptual growth in studies of science and technology. Laboratory studies that followed the initial studies built upon these conceptions in ways that continue to challenge science studies to this day. If one can get over programmatic preoccupations with epistemology, one can see that agency is where the action is in laboratory studies – and where it always has been.

Machines, Conventions, Culture: Agency in the 'First Author' Laboratory Studies

The epistemological project in laboratory studies can be traced to two initial projects, Bruno Latour and Steve Woolgar's *Laboratory Life: The Social Construction of Scientific Facts* and Karin Knorr Cetina's *The Manufacture of Knowledge: An Essay on the Constructivist and Contextual Nature of Science* (Latour and Woolgar, 1979; Knorr Cetina, 1981). The authors of these works enthusiastically enrolled themselves in the project of reworking understandings of the nature of science. In both of them, the stated goal of the ethnographic incursions behind the walls of laboratory science was to problematize demarcationist theories of science (efforts to draw a clear, logical separation between objective scientific knowledge and nonscientific beliefs) by unveiling the sociality at the heart of knowledge production. This project fit nicely with conceptualizations put forth by SSK scholars who had engaged with Wittgenstein's philosophical provocations and certain interpretations of Kuhn (Bloor, 1975; Pinch, 1982). Indeed, these first ethnographies of laboratory practice were considered the *coup-de-grace* for the

constructivist triumph, displaying what the philosopher-sociologists had been saying all along – that science was social to its core.

For their influential *Laboratory Life*, Latour and Woolgar entered The Salk Institute in San Diego on a mission. They held that their self-imposed naiveté about the actual nature of science would hold them in good methodological stead as they observed how facts were made by not biasing them toward the scientists' own accounts of their work. Their ethnographic conclusions, undermining the scientists' view that they were observing nature in the laboratory, were taken up readily, although often contentiously, in fields ranging from sociology and anthropology, to history, literature, and critical theory. Interestingly, while the terminus of the deconstructionist project was held up as the valorous result of *Lab Life* at the time, Latour and Woolgar's approach to agency can be seen to have set in motion a more important, longer lasting, and better sustained research arc in the STS field as a whole. While pursuing their stated interest in showing how facts are constructed, and while specifically putting aside some possible modes of agency, including the "administrative organization of laboratory work," the "influence of such organization on creativity," the "influence of laboratory organization on scientists' careers," and the "nature of communication and pattern of information flow" (Latour and Woolgar, 1979: 40), Latour and Woolgar focused in their early study on a mode of agency that would form the basis of the later formulation of the actor-network theory of Callon and Latour that would become a driving force in studies of science and technology – material agency. This agency is expressed through their notion of the 'inscription devices,' which Latour and Woolgar see at work throughout the laboratory. An inscription device is "any item of apparatus or particular configuration of such items which can transform a material substance into a figure or diagram which is directly usable" by scientists (Latour and Woolgar, 1979: 52). The crux of their conception of material agency is that:

> An important consequence of this notion of inscription device is that inscriptions are regarded (by scientists) as having a direct relationship to "the original substance." The final diagram or curve thus provides the focus of discussion about properties of the substance. The intervening *material activity* and all aspects of what is often a prolonged and costly process are bracketed off in discussions about what the figure means.
>
> Latour and Woolgar, 1979: 52, emphasis added

The most sustainably influential part of *Laboratory Life* was not its epistemological assertions about the construction of facts, but rather the conception that, while the scientists and technicians were busy writing down notes and figures in reference to other published and nonpublished notes and figures, the machines were busy writing too. Even if one does not take this 'material activity' as impugning the status of scientific facts (as many do not – including Latour himself later in his career), this germination of the idea of material agency, that technology itself has a hand in the shaping of human affairs and understandings of the nature of machines, would go on to enliven laboratory studies and studies of science and technology for decades to come, and also would lead to the removal of the word 'social' in the second edition of *Laboratory Life* (Latour and Woolgar, 1986).

In *The Manufacture of Knowledge*, Karin Knorr-Cetina also asserts explicitly that her project upended the demarcationist conception of scientific knowledge. Her view, as laid out in her programmatic essay 'Ethnographic Study of Scientific Work,' is that:

> The problem-solving model suggests that science is a successful tool for adequately coping with the world, even though we may not want to think of it as correctly representing the world. The vision behind this model is that of a decreasing stock of problems constituted by what we do not yet know about how to handle the world-out-there. The vision behind the constructivist programme as I conceive of it is that of a potentially increasing stock of problems created by science in the process of secreting an unending stream of entities and relations that make up 'the world.' The 'unknown world' as an intentional object of science is itself a function of a constantly changing scientific practice, of what at every moment of scientific work emerges as the known world. But this known world is a cultural object, a world identified and embodied in our language and our practices.
>
> Knorr Cetina, 1983: 135

For her part, Knorr Cetina points to two modes of agency that provide for the construction of knowledge. The first is similar to the material agency to which Latour and Woolgar point. For Knorr Cetina, technology, in the form of instrumentation that embodies and asserts previously made decisions, produces artifacts in the laboratory, not direct observations of nature. As with Latour and Woolgar, "instrumentally accomplished observations intercept natural courses of events" (Knorr Cetina, 1983: 119). This 'interception' is the manifestation of the material agency of the instrument(s). The scientific laboratory, then, "consists of materializations of earlier scientific selections; this accounts for its artifactual character" (Knorr Cetina, 1983: 121). For Knorr Cetina, however, this put-in-place technology is not as autonomous as it was for Latour and Woolgar. The instrumentation is itself dependent on previous human decisions. Elucidating this mode of agency was one of Knorr Cetina's important contributions to laboratory studies, and as with Latour, Knorr Cetina re-explored and elaborated on this core conception in future work (revising it more toward the autonomous agent that Latour and Woolgar proposed), which became very influential in studies of science and technology at large. This early divide between the laboratory studies of Latour and Woolgar and Knorr Cetina can be seen to presage debates between actor-network theorists, social constructivists of technology (SCOT), and non-SCOT for decades to come in STS.

In *Manufacture of Knowledge*, Knorr Cetina (1981) also pursues a second mode of agency specifically left unexplored by Latour and Woolgar, which she refers to as the 'trans-epistemic field.' Not satisfied with the loose and ubiquitous concept of scientific community, Knorr Cetina asserts that the larger and wider, supposedly external, organizational ties that, for example, have to do with funding and the administration of publications are not neatly cordoned off from the internal intellectual ties that bind a community of scientific

practitioners. In an early review of laboratory studies, Knorr Cetina notes that:

> Scientists, even specialty colleagues, may confront each other in their everyday exchanges in 'non-scientific' roles in which they administer money or decide on professional careers. Similarly, a government official or sales agent may negotiate with the scientific specialist the methods to be used in a research project, or the proper interpretations of a measurement result.
>
> Knorr Cetina, 1983: 132

For Knorr Cetina, the crucial question is in what sense these 'trans-epistemic connections' are relevant to 'the process of inquiry' in science. Her answer is that such connectivity is the second agent of fact construction. "These relationships emerge as the locus in which the decision criteria corresponding to laboratory selections … are defined and negotiated" (Knorr Cetina, 1983: 132). As with material agency, future laboratory studies would utilize and build upon Knorr Cetina's initial exploration of such distributed organizational agency, as she herself also would in her own studies. Regardless of how her assertions about the epistemic implications of her observations were pushed by her and taken up by others, this exploration into material agency and distributed organizational agency proved to be of longer-lasting influence in studies of science and technology, as both actor-network theorists and social constructivists of technology (now SCOTS) wrestled with incorporating systems of organization into their respective frameworks.

While Latour, Woolgar, and Knorr Cetina actively engaged themselves in the epistemological project of laboratory studies, Michael Lynch and Sharon Traweek made no such epistemological proclamations, although they were variously enrolled in the project by others (Lynch, 1985; Traweek, 1988). Using an ethnomethodological approach, which itself does not hold that scientific knowledge is social in the same sense as Latour and Woolgar, and Knorr Cetina proclaimed, Lynch focused on the contingent decision making of scientists on the 'shop floor' of the laboratory. This decision making was done by individuals in interaction with other individuals and investigative materials, and each successfully negotiated decision became the basis for further decision making, thus locking in the conversationally negotiated contingency. These conversational negotiations were not random, however, and here Lynch brings in a form of agency different from that of Latour, Woolgar, and Knorr Cetina. Yes, individual scientists are in the foreground of Lynch's analysis, but conversation is used by individuals to assert their positions, or will, on the shop floor of science, and in order to do so certain conventions of language and conversation must be adhered to. Here, the structure of the conversational conventions themselves, however loose, becomes an agent in the decision-making chain of laboratory practice. Although such conversational negotiations could lead to a wide variety of possible outcomes, owing to the momentary and contingent interactions, such interactions could not simply be random, or infinitely malleable. Rules of language were governing forces in interactions that built up to scientific claims. In this work, widely considered the epitome of micro-sociological studies, structural agency was in fact present, and would be taken up and pursued by later laboratory studies researchers.

Sharon Traweek states at the outset of her book *Beamtimes and Lifetimes* that exploring epistemology is not the purpose of her study, noting that her book is about how physicists "have forged a research community for themselves, how they turn novices into physicists, and how their community works to produce knowledge" (Traweek, 1988: 1). In pursuit of her project, Traweek brings out several different kinds of agency that are different from those featured in the other early laboratory studies, in that they are rooted in broader conceptions of culture. Traweek does see a role for a kind of material agency at the laboratory, albeit a different one from Latour, Woolgar, and Knorr-Cetina. For Traweek, technologies in the laboratory transmit not their own essence or logic, or reified versions of previous human decision making, instead they are cultural forces. The cultural agencies that she describes throughout her book can be, she notes, are asserted through the scientific instrumentation of particle physics detectors. For Traweek.

> (d)etectors express diverse styles of research, different strategies for success. Above all, they embody rules for separating noise, which arises from imperfections in the experimental process, from data, which carry authentic messages from nature; nevertheless, detectors ideally become invisible, transparent scientific instruments for reading news from nature. I see detectors as the material embodiment of the high energy physics culture.
>
> Traweek, 1988: 158

For Traweek, the cultural aspects of agency include gender, national culture, the culture of high-energy physics professionalization, and cultural conceptions of time itself. Her ethnographic approach to gender, working from the inside of the scientific laboratory outward and including her cross-national comparison of US and Japanese laboratories, was an innovation that spurred much important work in STS. Her inclusion of organizational practices, both national and professional, as an active part of conceptions of action in the laboratory among scientific practitioners is in line with Knorr Cetina's push to consider trans-epistemic fields, and was an important impetus for such considerations in subsequent laboratory studies. Her invocation of time as a conceptual driving force for scientific action was unique and creative. Overall, Traweek brought into play a cultural conception of agency, where individual practitioners negotiated cultural forces; forces that could also be transferred through the detectors themselves. These larger forces could be manipulated to a certain extent, as when certain stereotypes were broken successfully in the laboratory. But more so than the other early authors of laboratory studies, Traweek pointed to a prime-moving, nonmaterial agency at the laboratory that came from an inaccessible, and to a large extent immutable, cultural realm. As with the initial incursions into material agency and distributed organizational action, the role of cultural forces would also occupy actor-network theorists and SCOT(S) and non-SCOT(S) adherents as they endeavored to account for such obviously powerful, yet seemingly ineffable, driving forces.

Developing Agency: The Continuing Build-Up of Laboratory Studies

Following on the initial laboratory studies, subsequent researchers have built up, further refined, and further challenged conceptions of technoscientific agency. Karin Knorr Cetina went on to expand her conception of material agency, including both Latour and Woolgar's conception of independent material action and also Traweek's sensibility with regard to culture(s). Knorr Cetina codified a concept of 'epistemic cultures,' whereby different disciplines in science, by virtue of their differing instrumental configurations, produce distinctive "ontolog[ies] of objects and machines," as well as larger "'epistementalities' that prevail in the larger society – beliefs and attitudes about the correct distribution of knowledge, the rights of access to it, the requirement and meaning of transparency, etc." (Knorr Cetina, 2001: 8235). Thus molecular biology with its dispersed bench work practices and wet laboratories is culturally, epistemologically, and ontologically different from particle physics, with its large, centralized accelerators and detectors and the unified actions of hordes of scientists. Here, the machines themselves and cultural forces combine to distinguish the laboratory work of different scientific fields. Wrestling with Knorr Cetina's concept of trans-epistemic fields, but focusing on dynamics of change, Park Doing has proposed the concept of 'epistemic politics' to connect laboratory members' disciplinary negotiations (negotiations over laboratory resources, instrumentation, operations, and agreements on the proper nature experimentation) to modes of organizational reporting and strategies for sustained laboratory support, including funding, academic posts, public awareness and support, economic leverage, and control of peer review in scientific publication (Doing, 2009).

Considering trans-epistemic fields in a different way, Martina Merz has proposed the notion of 'technological platform' – like the concept of 'nanotechnology' itself – as a dispersed imperative that laboratories and organizations draw upon to bring together funding sources and intellectual resources (Merz, 2010). Continuing to consider organization in laboratory practice, Vincent Simoulin (2007) has also proposed redefining the notion of scientific community based on his study of interactions of 'research collectives' revolving around a synchrotron, and Hackett et al. (2004) have referred to the 'research assemblages' interacting at a Tokomak fusion laboratory. Morgan Jouvenet (2007) has been concerned with both distributed organization and professional culture in nanotechnology laboratories. Benjamin Sims and Christopher Henke have connected the larger politics of nuclear weapons stockpiling to the operation of, and assessments of the validity of, nuclear fusion laboratories (Sims and Henke, 2012). Sims also has brought in the driving force of 'safety' as a cultural imperative that determines conceptions of laboratory instrumentation and operations (Sims, 1999). Pushing into further explorations of larger cultural concepts, Traweek has expanded upon her previous notions of agency, building on her initial study as well as others by elaborating on the relationships between instrumentation, organization, culture, and individual self-conceptions that drive action in scientific laboratories. Traweek has opened her notions of agency to include conceptions of colonial culture, thus relating 'big science' laboratories to colonial centers of power analyzable with the tools of postcolonial cultural theory and initiating similar movements in studies of science and technology in general (Traweek, 1996, 2004). Most recently, following the impetus from feminist studies of science and critical theory, a movement is beginning to emerge that calls for an approach to studying laboratories that is tuned into and driven by the normative notion of political and cultural 'matters of care' (Puig de la Bellacasa, 2011).

Further wrestling with material agency, Matthew Hubert (2007) has explored relationships between identity and instrumentation in the hybridization of nanotechnology laboratories. Dominique Vinck and Gloria Zarama (2007) have wrestled with similar considerations during the merging of nanotechnology and microtechnology laboratories. Knorr Cetina and Merz have posed a particular challenge to considerations of material agency by following the work of theoretical physicists (Knorr Cetina and Merz, 1997; Merz and Knorr Cetina, 1997). What kind of agency is at play when no material at all is involved in the scientific work? Expanding conceptions of material agency from the instrumental, Thomas Gieryn has called for exploring the role of space in laboratories (Gieryn, 2000). How does the material agency not just of instrumentation and technological infrastructure, but also of the architecture of laboratories determine actions and conceptions of work inside of them? Thinking the other way, studies have also begun to wrestle with the role of the virtual laboratory in a world of increasingly linked and real-time communications (Sims et al., 2013). What is the implication for considering the laboratory as a place of no 'space' at all, where "the electronic space becomes a *workbench* for participants?" (Knorr Cetina, 2001: 8237). And, picking up on the early strand of conversational agency, researchers have explored the role of skepticism in real time laboratory practice and also pushed again on conversational modes of convergence in laboratory decision making (Owen-Smith, 2001; Sormani, 2014).

Carrying forth Traweek's initial impetus to consider the different 'kinds' of physicists in the course of a career, laboratory studies researchers have also sought to bring the ubiquitous presence of technicians in laboratories into considerations of technoscientific agency (Barley and Bechky, 1994; Barley, 1996; Lynch and Jordan, 1995; Orr and Barley, 1997; Doing, 2004; Bechky, 2006; Wylie, 2009). A driving question for these studies is whether technicians are fundamentally different agents than scientists themselves. Considering this question has challenged some long-held notions of both skill and expertise in STS as well as considerations of material agency. For SSK writers, tacit skill is the cornerstone of theories of the 'enculturation' of scientific knowledge (Collins, 1985). Uncodefiable tacit ability is the means by which the social is 'injected' into technical knowledge production by scientists, defining what it means to be a technical expert. Recent laboratory studies, however, have challenged that notion by noting how 'skill' is used as a political category variously asserted and performed by scientists and technicians as a means of cordoning off workplace authority and control (Doing, 2004) and managing disparate groups of laboratory interests (Wylie, 2013), or as an accounting device to rationalize practical action (Lynch and Jordan, 1995). If

tacit knowledge is not the epistemological cornerstone of enculturation, then on what basis is technical expertise sociological? A further challenge stemming from considering technicians in laboratories involves exploring material agency. What does it mean for material agency if scientists, and sometimes technicians themselves, see technicians as inscription devices? If a human is carrying out the material inscription, does that mean that a material agent need not be material after all, that some other, more specified, quality of action is what determines the 'materiality' of technological force?

In all of these investigations, agency is never a one-way street, or even a two-way street. Rather, these empirical investigations into technoscientific action in the laboratory are more in line with dialectical considerations of agency from social theory, such as Anthony Giddens' 'structuration' and Pierre Bourdieu's conception of the relationship between 'habitus' and 'field.' Actions are taken by motivated agents who variously conceive of themselves as able to act or as constrained by various forces 'large' and 'small,' 'human' and 'technological.' Any account of what actually drives the action has to wrestle with this kind of recursion. Since laboratory studies practitioners are so closely confronted with their subjects' accounts of themselves, this kind of recursion is necessarily at the fore of accounts of agency emerging from this kind of research. Of course, there is no 'grand unified theory' of agency – as continuing theoretical debates in social theory and STS make evident. But just how individual action, material agency, distributed organizational agency, and cultural forces manifest in recursive dialectic relation in the course of technoscientific practice at the laboratory has been the core project of laboratory studies from the beginning, even if was missed at the time, with many and new results arising from continuing investigations. As Vinck summarizes the supple kind of agency that drives the field:

> A laboratory is … not just an organisation that coordinates individuals or groups with recognised skills working on an identified socio-technical production, but a system in which objects, instruments and skills are re-opened, a system that is assessed through its ability to further exploration and extend questioning. It (is) especially interesting to examine the way these laboratories reconfigure the 'resources' they implement (money, groups of researchers, instruments, and partner relations in particular) in order to integrate these in new registers, and knowledge projects. These laboratories merge and redirect pre-existing socio-technical entities; they disconnect and transform these entities, settling them finally in a new universe of phenomena and relations.
>
> Vinck, 2007: 163

With such explorations into the relations between individual action, material agency, distributed organizational agency, and cultural 'forces,' laboratory studies continue to challenge theoretical debates between actor-network theorists, SCOT(S) adherents, non-SCOT(S) practitioners, cultural studies of science and technology, and newer proponents of the 'mangle' of practice (Pickering, 1995), all of which make up grist for the mill of STS research.

Conclusion

Key questions regarding technoscientific agency have been driving forces for, and still reverberate in, STS today. What is the nature and role of material agency? How might distributed organizations or systems constrain or affect technoscientific action? What role is there for larger cultural 'forces'? How might all of these agential impetuses conflict, relate, or recursively interact and intercede with one another? From the beginning, laboratory studies have put forth and wrestled with these kinds of questions. Since their main contribution was seen to have been with regard to the epistemology of scientific facts, rather than making sense of the steering of technoscientific realms, the importance of laboratory studies investigations to these kinds of questions was missed at the outset, and then largely ignored. Even so, laboratory studies practitioners first set the stage for theoretical debates about agency in STS, and then quietly and empirically dug into sophisticated conceptions of action that continue to be at the forefront of theoretical currents in the field to this day. The laboratory is, and has always been, where the technoscientific action is. Consequently, laboratory studies are, and continue to be, valuable resources for STS practitioners.

Abstract

Jacques Lacan was one of the most influential psychoanalysts in France. Lacan reinterprets Freud's early texts under a linguistic lens, concluding that the unconscious is structured like a language and that unconscious processes like condensation and displacement are equivalent to linguistic processes of metaphor and displacement. Lacan emphasized that the human being is a divided subject, split between conscious and unconscious processes, between language and speech, and constituted in and through language. Lacan redefines human existence as living in between the realms of the imaginary, the symbolic, and the real, covering all aspects of life that are visually and symbolically represented and capturing those that lie beyond grasp through the register of the real. Lacan's psychoanalytic theory is a theory of lack in which the human subject is held in his longings between a complex interplay of need/demand and desire. Lucan deduced that because every human subject is born dependent upon the Other, his subjectivity is shaped by the desire and the law of the Other since it is for and through the Other that human desire is founded. The father as the symbolic representative of law and culture and responsible for the separation of the child from his incestuous desire for and by the mother, is crucial in Lacan's reconceptualization of Freud's oedipal complex. For Lacan, the oedipal complex is not a developmental stage but a permanent structure through which the human being negotiates his desire within or outside the law.

Jacques Lacan, born on 13 April 1901 (Paris), was the youngest child of a family of Orleans-based vinegar merchants and was raised by a strictly Catholic mother and a father who was perceived to be rather weak. He was the eldest of four children, with one sister and two younger brothers, of whom one died, and the other joined a Benedict monastery where he became a priest in 1929. Lacan pursued his early studies at the prestigious Jesuit *College Stanislav* and began his medical studies in 1926, specializing in psychiatry at the *Sainte Anne Hospital*, Paris. During his medical studies Lacan broke with Catholicism and developed a growing interest for philosophy, especially the works of Karl Jaspers, Martin Heidegger, and Spinoza, and he attended seminars about Hegel given by Alexandre Kojeve. He also professed a strong interest in literary studies and art, in particular, in the literary works of James Joyce and the surrealist movement. He was close friends with Andre Breton and Salvador Dali and published some of his earliest writings in the surrealist magazine *Minotaure*. Had it not been for his particular French character, one who was interested in philosophy, history, and language, Lacan might have not been as successful as he was in introducing psychoanalysis to France, a country that had been highly suspicious of the foreign roots of psychoanalysis.

In 1931, Lacan received his license to become a forensic psychiatrist and in 1932, he started his training analysis with Rudolph Loewenstein. Within the same year he finished his dissertation on "The Paranoid Psychosis and Its Relation to the Personality" in which he analyses the case of a woman, 'Aimée,' who later turned out to be the mother of his initial companion and later rival Didier Anzieu, who became a prominent psychoanalyst in his own right. Aimée (the pseudonym for Anzieu's mother) had attempted to kill a famous actress whom she had imagined had spread slander about her, and Lacan had interpreted this attempted murder as Aimée's unconscious wish to merge her own image with that of an idealized other one, whom Aimée had thought to destroy in a wish for self-punishment. Aimée's case burgeoned Lacan's long-standing interest in paranoiac themes, such as jealousy, persecution, grandiosity and the essential importance of the image and its influence on the identity formation of the subject. In writing about this case that he had seen at the *St. Anne Hospital*, Paris, Lacan was greatly influenced by Freud's (1922) paper *Some Neurotic Mechanisms in Jealousy, Paranoia and Homosexuality*, which he also translated from German to French, a practice, incidentally, he maintained throughout his life, of translating papers from German or English to French, which were of importance for his psychoanalytic studies and publications. From Freud's text and the case of Aimée, Lacan took the idea that a paranoiac knowledge existed at the core of each subject and that the confusing image of the Other strongly shaped, as he would later formulate in his concept of *The Mirror Stage*, the formation of the ego (the 'moi imaginaire'). A painter, like Salvador Dali, strongly agreed with Lacan's basic tenet that a paranoiac mechanism exerted a strong force in the construction of each subject.

In addition to his collaborations with the surrealist writers and painters of his epoch, Lacan was also fascinated during his medical studies by his teacher, Gaetan Gatian de Clearambault, who had been a well-known forensic psychiatrist and an avid collector of photographs of North African female garments. However, he had become even more prominent through his 'spectacular' suicide since he shot himself in the head, sitting in front of a mirror, after he had learned that he was destined to lose his eyesight due to a retina infection. The tragic irony of Clearambault's specular suicide is not lost on most readers of Lacan's work since it powerfully illustrates the aggression underlying the narcissistic ego formation, which Lacan discusses in his concept of the mirror stage.

After 6 years of analysis, Lacan left his analysis with Rudolf Loewenstein in disagreement. He nonetheless joined

the Parisian Psychoanalytic Society (SPP) in 1938 and became a member of the SPP. At the 14th Congress of the International Psychoanalytic Association (IPA) in Marienbad in 1936, he presents his first analytic paper on "The Mirror Stage as Formative of the Function of the Ego." His presentation is disrupted by Ernest Jones, the president of the IPA, after 10 min, because he was unwilling to extend Lacan's slated presentation time. Lacan leaves the congress in protest and presents the paper 13 years later in its full and extended version at the Zurich IPA-Congress in Switzerland. Jones' autocratic behavior at this highly politicized congress set yet another signal to Lacan of the increasing influence the ego psychologists would hold over the developing psychoanalytic discourse. His own former training analyst, Rudolf Loewenstein in conjunction with Heinz Hartmann, David Rapaport, and Ernst Kris were pursuing a psychoanalytic path that was already highly suspect to Freud himself, and which focused on the powerful character of the ego and the therapeutic benefits that would be gained with the strengthening of the ego. In line with Freud's (1937) own late misgivings about the seeming normality of the ego, Lacan unmasks the ego as an illusionary and deceiving structure that alienates the subject from his or her unconscious desire. Instead of strengthening the ego, Lacan advocates the dismantling of the ego as a means of setting free the subject's unconscious desire, allowing the subject to speak its own truth. In 1949, Lacan writes:

> The mirror stage is a drama whose internal thrust is precipitated from insufficiency to anticipation- and which manufactures for the subject, caught up in the lure of spatial identification, the succession of phantasies that extends from a fragmented body-image to a form of its totality that I shall call orthopaedic-and, lastly, to the assumption of an armour of an alienating identity, which will mark with its rigid structure the subject's entire mental development. (p. 4)

Lacan defines 'The Mirror Stage' both as a developmental process and a permanent, 'rigid' structure through which the young 'infans' (that means without language) forms an image of his body through the *Gestalt* in the mirror which promises a more unified and complete body image than the child's actual motoric capacity. The young infant typically greets this more unified image with jubilation (*jouissance*) because the child recognizes in the mirror a body that holds out the illusion of a unity and mastery that he cannot yet physically experience but which sets him up on an anticipatory level for a desire to reach for a more complete specular version of himself than he is capable of. The tension between the perceived image and the body creates a phantasma of a body felt to be in pieces (*fantasme du corps morcelé*) which appears in psychotic regressions or also at moments in the psychoanalytic treatment when certain levels of awareness are reached. The unified image the child prematurely obtains is always at risk to fall apart and threatens to haunt the subject in his own subjectivity. While the mirror stage was held to be initially a primarily specular process, where the infant identifies with the image projected ahead of him and mistakes that image to be himself, Lacan later also always emphasizes that this imaginary process unfolds in the presence of an Other, a third who speaks to the child and identifies him as the child in the mirror. "Look who is there, there is little Peter." Through the language of the Other, typically the mother or father who holds the infant in her/his arms, a symbolic identity is introduced intertwined with the imaginary one. In the moment of the parent saying or expressing to the child something like "This is you!," a triangulation takes shape in terms of the imaginary, symbolic, and real registers, the image, the word, and the referent. With the mirror stage, Lacan not only expands Freud's concept of the ideal ego and ego ideal, but he also provides a radically new idea about the process of identification as a specular, desiring, and alienating process where the 'I is the Other.' By unmasking the ego as an agent of deception, Lacan also pays tribute to Freud's late realization that the ego is not normal but shares many characteristics with the psychotic, as Freud describes in his 1937 text, *Analysis Terminable and Interminable*.

During World War II, and while The Société Psychanalytique de Paris was closed by the Nazis, Lacan served in the French army at the Val-de-Grace military hospital in Paris. By the beginning of the war, Lacan had been married for 6 years to Marie-Louise Blondin and had fathered two children, his daughter Caroline, born in 1934 followed by his son Thibault in 1939. In 1940, a third child, Sibylle, was born. However, a year later, Lacan fathers another girl, Judith, with another woman, Sylvie Bataille, the estranged wife of George Bataille, whom he marries in 1953 after having divorced Blondin beforehand. Judith, his youngest daughter, will become later very important for the transmission of her father's work together with her husband Jacques-Alain Miller. He will be in charge of Lacan's publications and distributions of seminars after Lacan's death in 1981.

Due to his appeal for a return to Freud and his earlier writings, Lacan comes to the forefront of the international psychoanalytic scene in the 1950s. This appeal is linked to an intensive focus on the philosophical thoughts of Heidegger, the linguistics of Ferdinand de Saussure, and the structuralistic concepts of Lévi-Strauss. Lacan's postwar writings are increasingly focused on the theory of the symbolic register, language, speech and the fundamental concept of the Other as a representative of the law, culture, and the storehouse of signifiers. Rereading Freud's early texts, like *The Interpretation of Dreams* (1900), *The Psychopathology of Everyday Life* (1901), and *Jokes and Their Relation to the Unconscious* (1905), through a lens of structuralism and linguistics, brings into sharper focus the fact that the human subject is primarily constituted in and through language and that this language which precedes the subject, speaks the subject as well.

In the above mentioned essays, Freud not only discovers the laws and rules of the *primary process* as the structure of the language-like psychoanalytic unconscious, but he also proves himself to be a forerunner of modern linguistics by representing conceptions that relate closely to the later school of semiotics, in particular to the work of Saussure and Roman Jakobson.

With the discovery of the mechanisms of condensation and displacement which are so essential for the work of dreams, jokes, and parapraxes and which will later be conceptualized as metaphor and metonymy in the field of linguistics, Freud provided not only the basics of a rhetoric which illustrated the poetic aspects of the unconscious but also the principles of signification in any language.

Identifying the unconscious as a linguistic mechanism led to the understanding that thinking and speaking were not hierarchized activities, but processes which were mutually constituting themselves. The human language does not consist of deep structures that shape thinking or the oral expression of words, but it is instead constituted by what Saussure calls 'signs,' which are elements that combine sounds with concepts. The concept is called the signified and the sound of the word is called signifier. The sign is not a primary name that identifies an external phenomenon, but it consists instead of a combination of a signifier and signified, which are related to one another in an arbitrary way. Language is thus no longer thought to be representational, but primarily conceived in terms of articulation, in terms of sounds relating to one another in an arbitrary fashion. Language, conceptualized in terms of articulatory principles, is governed by a constitutive law of difference, represented by the symbolic order, and held in contrast by the constitutive law of similarity, which is instituted by the register of the imaginary. The relationship between signifier and signified is arbitrary and codetermined by social conventions/understanding/agreement. For instance, signifiers and signifieds alike exist because they are something, which others are not. Sounds, in other words, single letters can only function as signifiers as long as they differentiate themselves from others. A thought or concept can only become a concept/thought as long as it is different and separate from another. Binary opposition and differentiation mark the structure of an articulated speech.

Unlike Saussure, who privileged the signified over the signifier, Lacan reverses this connection, and sets the signifier over the signified, underscoring thereby the importance of sound over an agreed-upon social meaning. Lacan also wanted to place particular importance upon the signifier's ability to shift between meanings because without this ability, a joke or a dream cannot properly function. We hear, for instance, the word 'wait' and can hear the word 'weight' at the same time, and it is this sliding between sounds in each language that accounts for the multiple layers of meanings between words embedded in each language. In addition, Lacan wanted to emphasize that speech comes before thinking in the development of the human being, and that the human subject is already spoken and phantasized about long before his actual birth. He is impregnated by the parents' conscious and unconscious wishes, desires, and expectations and is thus intrinsically captured in his being through the language of the Other. The human subject is not dominated by language, but he is constituted in and through language.

Lacan places at the forefront the double birth of the human being – of the 'I' (Ego/moi) through the specular identificatory process during the mirror stage, and of the subject (je) through the determination of the signifier in the acquisition of language. The human subject is however furthermore alienated through his premature birth and his subsequent fundamental helplessness which Lacan connects with Heidegger's notion of 'Seinsverfehlung' and translates as 'manque-a-etre,' which is akin to the English neologism 'Want-to-be.' Lacan's psychoanalytic theory can be conceptualized as a theory of lack for which culture is destined to complement the deficits of the human drives and his essential drivenness.

With his theory of the double birth of the human being as an imaginary ego and a symbolic subject (corresponding to the myths of Narcissus and Oedipus), Lacan introduces an object relations theory with medial dimensions running parallel to Freud's drive theory. As categories of representation the imaginary and symbolic realms capture the internal and external world of the human being in permanent modifications, while the real as a third dimension covers all those aspects of the human world that cannot be symbolized, are not mediated and are beyond human grasp. Lacan will devote the last part of his theoretical work to the workings of this register of the real, and devote his clinical focus upon the various aspects of the human's use of *jouissance* as a kind of excess pleasure going beyond images and language, not undergoing symbolic castration, which implies the acceptance of an inevitable lack of being.

In contrast to Freud, but in agreement with Melanie Klein, Lacan situates the oedipal complex in the early development of the child. During the third phase of the mirror stage, around the 14th month of his life, the baby enters into the part of the early stage of the oedipal complex as he is gradually identifying his bodily 'moi' with the image projected of himself by the outside world. Since the young infant is born prematurely and is therefore totally dependent upon the help of the Other, he is dependent upon the desire of the mother. In experiencing this desire the child strives to be the object of the desire of the Other, thus identifying with the fundamental maternal lack and unconsciously with the desire to become the mother's phallus. Eventually, the father intervenes into this imaginary triangle as one who spoils this game of illusionary omnipotence between mother and child. He intervenes as the representative of the law and culture and forbids the child his phallic identification and thereby also prohibits the mother to use her child as her phallic substitute. Lacan identifies the appearance of the father as the representative of the law as the second step in the oedipal complex.

During the third phase of the oedipal complex, the child is supposed to identify with the father and to submit himself to the symbolic order, the order of language. The father is identified as the carrier of the word and the representative of the law, but he has to be credible in this symbolic function in order to be accepted as the 'nom-du-père.' 'Nom' and 'Non' – the two signifiers sound alike and combine the function of the father in one word as the one who has to act in his own name when he says 'no' to the mother/child phallic dyad. The mother has to accept the father as a representative of the law so that the child can accept the name of the father as well. If there is no maternal recognition of this symbolic father and if the child refuses the law, the imaginary predominates and the child remains submitted to the mother (neurosis or perversion). In the worst case, which is the case of psychosis, not only is the process of *separation* lacking, but also the process of what Lacan defines as *alienation:* the child functions as a real part of the dyadic and symbiotic mother–child relationship and therefore will not really arrive at a clear differentiation between the self and the Other.

If, however, both mother and child accept the paternal law, which does not have to be represented by a real father figure, but can be assumed by another figure or instance filling out this symbolic position, the child identifies with this third element supposed to carry the phallus as something the mother is

longing for outside of the child himself. The symbolic father is the one to place the phallus in its rightful position. He marks the phallus both as a desire of the mother and as a signifier of a principal lack. Nobody really possesses the phallus, as the identification of the phallus with the masculine penis proves to be the result of an illusionary misjudgment. The child is no longer the one the mother lacks, it is other and instead of being a desired object it becomes a desiring subject. Through an identification with this Other, the child enters into the category of having and leaves behind the primacy of being.

The movement from being to having is a symbolic castration: The father castrates the child by differentiating him from the phallus and by separating him from the mother. With this shift the child becomes a subject who differentiates himself from the other two subjects. As the child moves from the imaginary to the symbolic register, his counterpart also changes from being a double to becoming a speaking Other. However, even the symbolic castration does not abolish the internal subjective division because the subject remains still alienated after his specular identification, since he can neither find a 'Seinsgrundlage' (ontological fixation) in speech. He is also only represented by the signifier referring to another signifier, or, as Lacan writes, that "… a signifier is that which represents a subject for another signifier" (1978: p. 207).

When the subject says 'I,' his division becomes obvious, he is at the same time the subject of his enunciation and subject of his expression. Lacan identifies the mature subject as a permanently divided subject and symbolizes that division through a bar of the subject: $\$$.

As the incestuous desire for the mother is being repressed through the installment of the name of the father, the phallus as a sign of lack is also repressed. The repression of the phallus is equivalent to primary repression, which constitutes the unconscious and initiates secondary repressive mechanisms. In this constitutive process, the signifier of lack, of a border, and of a prohibition is anchored in the unconscious. The infantile wish to be joined with the primary Other is forever repressed, which does not mean that the human subject does not continue to keep looking for it and to find only substitutes for it in its place. In this way, the wish turns into the unsatisfiable desire which so characterizes Freud's notion of a wish and which is part and parcel of Freud's definition of the unconscious. Since desire is embedded in this open system of language – where a signifier always points toward another signifier, which means that meaning can never be limited, Lacan comes to the conclusion that the unconscious is not just made of desires (wishes), but that it is also constructed like a language. The unconscious can be seen as a site of repressed and displaced signifiers, which began to be formed through the repression of the fundamental signifier of the phallus.

The signifiers belong to an order of letters – sound letters – and are therefore less bound to a system of meanings or sense. Lacan references Freud's idea that the dream uses signifiers through condensation and displacement to shift and distort meanings to evade the censor, and this work of distortion is less guided by a system of contents but rather by a system of formal structures. The unconscious is a system of writings as Freud already described it in Letter 52 to Wilhelm Fliess in 1896 when he identified the unconscious as an apparatus of 'Niederschriften' (written inscriptions). Language and writing come from the outside, come from the Other who speaks. For this reason, Lacan also defined the unconscious as The Other who speaks (and writes) in us and by whom we are also spoken (and written).

As a consequence of these considerations, Lacan differentiates between *need*, *demand*, and *desire* which constitutes his detailed elaboration and reworking of Freud's drive model. To begin with, one has to remember that each drive is a partial drive, which is bound to a particular erotogenic zone. Even though the genital drive is the one to privilege sexual strivings, other drives are also sexually bound. Each drive is also an amalgam of *eros* and *thanatos* because the moment the drive is satisfied, it works toward its own self-destruction. As Freud already described in *Beyond the Pleasure Principle*, the human being is also mortal through his sexual procreation. In order to repress the destructive part of the drive, the drive has to be blocked, tamed, and pushed back. In Lacan's writings, the drive is primarily bound to the lack (*manque*) to the exigencies of life (*Not des Lebens*) as Freud formulated it. The drive expresses itself initially as a need which forms a closer link to the psychosomatic than to the psychic life because it does not necessarily require a subjective experience to be registered intrapsychically, as is the case in an insulin coma for instance, where the body's need for glucose bypasses any intrapsychic awareness.

Pure need aims at an object and finds satisfaction in it. The infant's first needs can only be satisfied through another person, primarily hunger which is satisfied through nursing and here the infant encounters for the first time a forceful power over which the mother wields because she can give and withdraw her breast as she sees fit. Lacan focuses on this power which installs itself prior to the satisfaction of needs and transcends the satisfaction or deprival of needs, which in turn points to the dynamics of what Lacan calls 'the demand.' Demand is not really concentrated upon real objects but is essentially focused upon a demand for love and exerts itself through presence and absence, through giving and withdrawing the longed-for love. The early helplessness of the young infant is the source of this demand which Freud had described as follows:

> The biological factor is the long period of time during which the young of the human species is in a condition of helplessness and dependence. Its intra-uterine existence seems to be short in comparison with that of most animals, and it is sent into the world in a less finished state…The biological factor, then, establishes the earliest situations of danger and creates the need to be loved which will accompany the child through the rest of its life.
>
> 1926: p. 155

The power, which distorts the access to the object, has a tendency to debase and minimize the need for satisfaction and to destroy the demand for love within the same act. A consistent misrecognition for a demand of love can have disastrous consequences as one can see in cases of anorexia nervosa. Lacan asserts that in anorexia nervosa, the child is always given what the Other one has (nutrition) but is not given what the Other one does not have, which is love. As a result, the child refuses any nourishment and sets into play a complex dynamic of refusal and desire.

Desire is the third term Lacan enlists in his triadic structure of need, demand, and desire and it is most akin to Freud's concept of a wish (Wunsch) that aims in the unconscious for something that cannot be satisfied. Lacan's assertion that "the desire is the desire of the Other," which means that we receive the desire through the words of the Other and that what we desire is always other, is always different.

While working on these different psychoanalytic concepts in the 1950s and developing a new body of psychoanalytic thinking through a simultaneous return to Freud's early texts, Lacan encounters during these productive years several conflicts with other psychoanalytic institutions. In the early 1950s a crisis erupts in the 'Société Psychanalytique de Paris,' which eventually leads to a division that is primarily based upon the question of lay analysis. Due to his code of analytic practice, in particular, the variable duration of analytic sessions, Lacan joins the liberal group around Daniel Lagache – much to the discontent of his own orthodox institute. This group develops into the 'Sociéte Francaise de Psychoanalyse' and is established as the second Parisian Association in 1953. In Lacan's opposition to American ego psychology he is strongly supported by the child psychoanalyst Francoise Dolto. However, as a result of its controversial stance, the group loses its membership in the IPA without either wanting or noticing it.

After long and difficult years of negotiations for reentry, the IPA demands Lacan's and Francoise Dolto's expulsion as trainees. In 1964, Lacan finally founds his own school called 'Ecole Freudienne de Paris.' Thirty-four articles by Lacan are published as 'Ecrits' in 1966. During 1966–76, Lacan frequently travels throughout the United States for the purpose of lecturing. Due to Lacan's teachings, the University of Paris VIII founds a department for Psychoanalysis in 1969, offering a psychoanalytic doctoral program. In some way influenced by the students' revolts of 1968, Lacan develops his theory of discourse as an attempt to insert his concept of the unconscious into social relationships. In 1969, Lacan also introduces the so-called 'passe' for the training of psychoanalysts. This special type of accreditation, however, is not recognized by everyone and, as a result, some of the members leave the school in order to establish their own psychoanalytic society ('Quatrième groupe').

During the last years of his life, Lacan is preoccupied with topology and mathematics in order to grasp the dimension of the real with its elements of the 'thing' (la chose, near to Freud's 'Ding') and the object 'a,' attempting also to elaborate the very connections between the categories of the real, the imaginary, and the symbolic. At the same time his 'Ecole Freudienne de Paris' is increasingly weakened as an institution due to the assumption that Lacan is no longer capable of acting in his own name, because of his son-in-law's, Jacques-Alain Miller's, supposed takeover of Lacan's school. In 1980, the school is finally closed as an act for a new beginning. Shortly before Lacan dies due to a malignant intestinal tumor on 9 September 1981, the school is refounded as 'Ecole de la Cause Freudienne.' Abstract

Secularization is nowadays the preferred term to describe the movement of societies away from the cultural or political dominion of a particular religion or of a sometimes competing set of religious beliefs. This article argues that a distinguish is usefully made between secularization and laicization, the latter being the largely political process that accompanied the growth of toleration and religious liberty in Western Europe after the end of the wars that accompanied the Reformation. The concept and its history are explored in this article.

During the second half of the twentieth century, sociologists often used the notion of *secularization*. This notion was basically seen as the decrease of religion's influence on modern society. Nowadays, not only can one notice that the decrease is not complete but one can also criticize the notion of *secularization* for being too broad. Often, this notion includes both a cultural and a political process, causing some confusion: for Gill (2008) in several cases, the origins of 'religious liberty' are essentially based on 'the political interest' of rulers. For a better understanding, one might want to distinguish two processes, a dominant cultural and social one (secularization) and a prevailing political one (laicization), without ignoring the interactions between the two.

When the process of secularization is predominant, the relative decline of religion's influence takes place in parallel with other evolutions, with no major tensions between religious and political, or other social forces. Certainly, religious changes, as well as economic, political, and other changes, may produce internal tensions. But, when all is said and done, the triumphant forces participate in the same social dynamic. Therefore, there is no important clash between the changes within the religious sphere and other social changes. For that matter, Scandinavian countries are a typical example of a dominant process of secularization. The switch to Lutheran Protestantism, particularly linked to the Bible's translation, favored the development of a national culture. Theological arguments ('theology of the two reigns,' absence of essential differences between clerics and laymen, rejection of papacy, etc.) have allowed the autonomy of the Nation-State toward religion not to provoke important conflicts. Moreover, a joint and progressive democratization of State and Church has taken place. A national church has emerged – this continues to be the symbol of the identity of nations that have been largely secularized.

The prevalence of process of laicization differs: the tensions between various social forces take on the aspect of an open-conflict where the religious becomes a political stake. The symbolization of the national culture, among others, is politically controversial. The State either imposes religion to society (*clericalism*) or it prevents religion from being the symbol of national identity (*laicization*). The French case is the main example of such a process.

Revolution in France and After: The First Threshold of Laicization

In France, the roots of this conflict are the results of the religious wars (sixteenth century) as well as the persecution of Protestants and dissenting Catholics (Jansenists) (end of the seventeenth century and eighteenth century). As a reaction to this, a certain antireligious dimension appeared in the French philosophy of Enlightenment. This spirit differed from the English Enlightenment (or the German *Aufkärung*). The latter appeared as a confrontation within a diversified Protestantism, wanting an 'enlightened religion;' the former directly attacked the Roman Catholic Church, '*l'infâme*' as Voltaire wrote, who was a deist.

In 1789, religion pervaded French society. The monolith Roman Catholic faith was made compulsory for the French people. The Catholic Church was an inclusive institution with power over other institutions, which often only existed in embryonic states. The monarchy had a religious justification with the theory of the divine right of kings. The king possessed a politico-religious power and the defense of Roman Catholicism was one of the monarchy's basic duties. But gradually monarchy also established a large autonomous political and administrative structure. A Gallican movement developed the idea of a French Catholic Church, which was autonomous from the Pope, protected and controlled by the State.

The first collapse came with the *Declaration of Human Rights*. It proclaimed the principle of religious freedom (1789), which was progressively applied to minorities. The Constitution divested the monarchy from its religious character. The monarch had a contract with the nation. The fact that the King did not respect this contract led to the conflictuous establishment of the Republic (1792). The state no longer had religious foundations. At that time, a breach between the Catholic Church and the Revolution appeared. There were three reasons for this: the proclamation of religious freedom, the bill of the Civil Constitution of the Clergy (1790), which fostered Gallicanism, and the establishment of civil registers for births, marriages, and deaths. The 'religion of the Fathers' could not embody the new society any longer, and the antirevolutionary propaganda became associated with Roman Catholicism. By the year II (autumn 1793), the institution of revolutionary cults went with

a violent struggle (period of the Terror) directed against revealed religions.

Napoleon Bonaparte inherited a chaotic situation. He thought it would be possible to restore the Roman Catholic Church and maintain some of the Revolution's great achievements. A Concordat was signed with the Pope (1801). The Roman Catholic Church was proclaimed 'religion of the great majority of the French' but did not have the status of a state religion; the 'Organic Articles' recognized two Protestant Churches (Lutheran and Reformed) (1802) and the Jewish religion (1807). In 1804, the Civil Code had no reference about religion: civil laws were generally secular (*laïque*) even so France was relatively unsecularized.

It is possible to assess this situation, using the abstract notion of the first threshold of laicization (constructed on the basis of Weber's ideal type), which was the permanent result of revolutionary upsets and is marked by three characteristics:

1. *Institutional fragmentation*: Roman Catholicism was no longer an inclusive institution. Religious activities were more and more clearly distinguished from 'profane' activities. Education and health gradually became autonomous sectors, with specific institutions that were going to develop progressively.
2. *Recognition of legitimacy*: The Revolution did not destroy religious needs that continued to exist objectively. The service provided by religion was a public service and the state paid ministers of recognized religions. Religions were socially recognized as a foundation of social morality.
3. *Religious pluralism*: The state recognized four religions; it protected and controlled them for they could satisfy the religious needs of their followers and develop moral values. Other religions were more or less tolerated. Relative freedom was even given to those who decided to do without 'the help of religion.'

The French Revolution did not succeed in establishing a durable system of separation of Church and State whereas the American Revolution did. In the United States, the Declaration of Independence stipulates that all human beings *are created equal, that they are endowed by their Creator with certain unalienable Rights*, which is not the case in the French Declaration of Rights. Why? Because in the United States, religious pluralism allows the dissociation of God from every church.

In France, religious monopoly would let the Roman Catholic Church become the owner of human rights, being the mediator between God and the Humans. This creates a structural difference in the long run. The American situation may have specific characteristics linked to the major function of religion: a social space for cultural pluralism. Stephen Warner (1993) indicates the main differences:

1. Religion is constitutive for some American subcultures.
2. Religion in America has historically promoted the formation of associations among mobile people.
3. Religion in America serves as a refuge of free association and autonomous identity, a 'free social space.'
4. The second generation of immigrants often transmutes ethnicity into religion because it allows assimilating and conserving their identity.

From the First Threshold to the Second Threshold of Laicization

In France, the compromise of the first threshold of laicization delineates a logic that dominated for almost a century. But the situation was not static. At first, this was due to the fact that at the beginning of the nineteenth century, a number of aspects of the first threshold were not entirely concretized: other institutions were not sufficiently developed to become totally autonomous. Then, especially during the second half of the nineteenth century, there was a growing political–religious conflict between the proponents of revolutionary values and those who considered France mainly as a Roman Catholic nation.

The first conception won. During the 1880s, the Republicans introduced a religiously neutral state educational system, which included a *morale laïque* (1882). At the end of the century, a new crisis arose from the Dreyfus case. The impression prevailed that the Republic was threatened by the *clerical peril*. The important law of 1901 on voluntary societies excluded religious congregations from the right to associate freely. The separation of Church and State appeared to be inevitable and took place in a climate of violent confrontation. But two models of separation were possible. One model was antireligious and combative. However, it was refused, especially by Aristide Briand and Jean Jaures, socialist leaders, who hoped to pass a law that would bring peace and eventually make it possible to fight social problems. A liberal model prevailed, ensured the freedom of conscience, guaranteed the free exercise of religion, and respected the self-organization of each church (art. 1 and 4) even though it neither recognized nor paid subsidies to any religion (art. 2). This marks the end of the system of *recognized cults*.

Even in liberal dominance, this model of separation, after the religiously neutral educational state system, found a new logic. This can be seen as the second threshold of laicization. As for the first threshold, there are three characteristics:

1. *Institutional dissociation*: Religion was entirely optional because it was no longer considered as the institutional structure of society but rather as a mode of free association;
2. *Social neutrality concerning religious legitimacy*: Religious needs became a private matter and public morality officially *laïque*. The question as to usefulness of religion for society was no longer publicly relevant. (In logic of the conflict, the opponents to Roman Catholicism asserted that religion and religious morality were dangerous for the Republic and its ideals. Neutrality was a compromise.)
3. *Freedom of religion*: Various religious societies belonged to the sphere of public liberties. The state guaranteed each citizen freedom of conscience and allowed each one to meet with religious societies or associations.

The separation of 1905 was marked by a twofold aspect: the victory of the *laïque* camp in the hard and long political–religious conflict of the *two Frances* and an implicit covenant with opponents. The conflict ceased progressively because religion was not a political problem any longer. The *Résistance* united unbelievers and believers in a common struggle. By 1945, the bishops held that there could be a positive meaning to the term *laicity* and, the following year, *laicity* was

officially proclaimed by the Constitution. It was a tripartite government – communist, socialist, and MRP (a political party that is close to Christian Democracy) – that included *laicity* in the Constitution.

Laicization in Various Countries

Other countries also show cases of processes of laicization with analogies with the French case as well as specificities. Here are three examples. At first, Belgium became an independent state in 1831, in a 'unionist' atmosphere, which gathered Catholics and Liberals, rather than anticlerics. The outcome was a regime of separation-recognition, accompanied by 'recognized cults' (but no Concordat) which tended to resemble the first threshold of laicization in France – this was possible because the situation was more democratic than that under Napoleon Bonaparte. In 1879, the Liberals attempted to create a *Laïque* school but the Catholic Party, victorious at the 1884 elections, progressively abolished these measures. Therefore, Belgium was never situated in a similar logic to the French second threshold but slowly integrated *laicity* and *laïque* morals in its system of 'recognized cults': 'nonconfessional' morals classes, *laïque* advisers in hospitals or prisons, *laïque* youth fetes that were similar to the first communion, etc.

For a very long time, Spain lived through a refusal of laicization of any sort. The 1912 Constitution declared that "the Nation's religion is (…) the Apostolic and Roman Catholic religion, the only real one." But in the 1931 Constitution, the Spanish Republic imposed both elements of the first French threshold (abolition of the Catholic religious monopoly, institution of the civil marriage) and of the second French threshold (separation, *laïque* schools, suppression of the religious symbols on public buildings) and even a few measures that go beyond the second threshold in France (for example, chaplaincies were suppressed). During the Civil War, this laicization resembled more the situation of the French Revolution than that of the Third Republic. The issue lied in Franco's national Catholicism, which reaffirmed Roman Catholicism as 'the only real' religion. Nevertheless, since 1978, there has been no State religion but 'relations based on cooperation with the Catholic Church and other confessions.'

The Italian situation of the mid-twentieth century was more ambivalent than the Spanish one but was not *laïque* either. The 1948 national reconciliation respected the agreements of Latran (1929), which had been a compromise between the Fascist regime and the Catholic Church. On the other hand, at the same time, it asserted the mutual independence of the State and Catholicism (State religion). This lasted until 1971, when the constitutional court asserted the priorities of constitutional norms on the agreements with the Catholic Church. After that, Catholicism ceased to be the State religion, divorce was authorized, and in 1984 the Concordat was renegotiated and an official pluralism began to exist.

Today's Spanish and Italian systems tend to resemble a laicity that stands between the first and the second French thresholds of laicization. On the other hand, England possesses an established Church that coexists with a maintained Catholicism as well as nonconformist Churches. This constitutes an original variation of the process of secularization. As early as the end of the seventeenth century, politico-religious conflicts no longer took place. In Germany, after the Thirty Years' War, the main process was that of secularization but it also integrated elements of laicization (*Kulturkampf*, in particular).

We then could think that the French situation is the most laïque but this is not the case. The Mexican process of laicization was built in direct opposition to the Catholic Church (Blancarte, 2008). Established since 1859, the separation between State and Church in Mexico became even more drastic and controversial toward religion in 1917. The Constitution showed, for example, that State education 'should remain absolutely away from any religious doctrine' and should fight 'fanaticism and prejudices.' It banned monastic orders, made sure that religious ceremonies only took place in Churches, which 'will always be under the authority's supervision,' and it refused the ministers of cult the right to vote, etc. Some measures were progressively eased, but the Mexican laicity remained stricter than the French one until 1992. Perhaps one could consider it as an anticlerical system rather than an example of laicity.

The Turkish process of laicization is also a stronger one (Kuru, 2009). In 1924, Mustapha Kemal Ataturk removed the caliphate and closed many religious orders. *Laicity* was officially stated in the Constitution in 1937. At that time, religious signs were restricted in public space. In Turkey, even if a moderate Islamic party governs now (2012), the state is separated from religion. But Islam, the largely prevailing religion, is supervised by the State Department of Religious Affairs (*Dianet*) and is not really separated from the state.

New Problems and the European Construction

Nowadays, whatever the degree reached in laicization, various societies must face new problems. For example, a dynamic element in the laicization process encouraged the development of laws about morals, independently from religious standards (like divorce in Catholic countries). Country rulers had believed in the progress of science and its capacity to maintain the social link. But, presently, above all, science is understood as a *techno-science*, the functional efficiency of which is undeniable but which, if it helps to resolve moral questions, also created new ones, difficult to resolve because of their intrinsic power. The development of genetics is significant, and in bioethical committees, some religious representatives are asked to give their point of view. In today's society, there are various debates on morals: questions concerning abortion, gay marriage, euthanasia, etc., are brought up.

In several secular states, similar to the United States and South American countries, the question is: Is religion a legitimate basis of morals lawmaking in a democracy? Many people contest the ban of life's choice or some pressures which are exercised to force them to accept religious ethical standards as 'natural' ones for all.

But for political current affairs, the prevailing debates often concern directly laicity and Islam: for some immigrants' children, this opposes the secularized culture that is taught at school and an orthodox Islam, transmitted by preachers, which seems to them a possibility to discover their roots through

original tradition. In France, but also in other countries, the *burqa* and *headscarves affair* are a typical example. Those supporting a ban argue that Islamic clothes are a symbol of women's repression, although the women themselves protest that it is 'their right and their religion.' But these affairs find significance, also by showing how difficult it can be for the immigrant populations of Muslim faith or origin – who often settled in the outskirts of a city, areas that are prone to break up and directly subject to increase employment and the crisis of the Welfare State – to integrate.

Moreover, the relations between the State and religion, in most of the countries of the European Union, tend to become a specific case of a larger European model. Italian Professor Silvio Ferrari defines it with the following coordinates (Ferrari, 1998):

1. The State is impartial toward the various individual religious citizens.
2. A religious subsector is singled out within the public sector. This may be understood as a playing or protected area field. This is the area in which lay most of the differences between France and the other European countries, because in France this area is not institutional.
3. The State has the right to intervene in this area only to see that the players respect the rules of the game and the boundaries of the playing field.

This model is deeply rooted now in the political and legal culture of contemporary Western Europe. It is ingrained to such an extent, that it has become the basis for the very formulation of the laws in force concerning religious liberties and church–state relationships. This may be seen both in internal conventions and in the constitutional laws of the main European nations. These conventions and laws are formulated to ensure the impartiality of the public powers, which are legally bound to respect the freedom to profess any religious faith (besides art. 9 of the European Convention of Human Rights) and to avoid any discrimination based on religion (art. 14 ECHR). With such a supranational legal situation, secularization can be put side by side with elements of laicity by diminishing the differences linked to the existence of an official religion.

To conclude, the ideal type of laicity can first be characterized as a twofold refusal: the refusal of an official religion, the standards and prescriptions of which would be imposed on all by means of civil law with the state's affirmation of religious neutrality, and the refusal of an official atheism which would limit religious freedom. More positively, laicity can be seen as a close relation between the freedoms of conscience and the freedom of thought. The freedom of conscience implies that every individual has the right to believe or not to believe, to retain or to change his beliefs. Therefore, the freedom of conscience leads to the pluralism of beliefs and philosophies within society. The freedom of thought implies that none of these beliefs or philosophies are privileged or imposed by the State, to the detriment of other convictions. The State is to respect them all and is to make sure that they can all be expressed freely.

Land Change: The Merger of Land Cover and Land use Dynamics

William J McConnell, Michigan State University, East Lansing, MI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article considers the merging of scientific perspectives directed at understanding land-use practices and the social and natural environments that shape, and are shaped by, them. While land cover refers to the biophysical attributes of the earth's surface and immediate subsurface, land use refers to the human imprint at a given location, both in terms of the modification of the land cover that would otherwise exist, and of the driving forces for such modification. Land change models aim to explain past land change, often with a view to projecting possible future dynamics.

The Integrative Study of Land Change

Land change science is concerned with land-use dynamics and with the social and natural environments that shape – and are shaped by – them (Turner et al., 2007). Previously known as land-use and land-cover change, conveying the conjoint nature of this branch of human–environment research, the current appellation reflects the coalescence of an integrated field of study aimed at estimating past human impacts on the earth, often with a view to projecting possible futures.

While closely related, the terms land use and land cover refer to quite different dimensions of the earth's surface that have traditionally been investigated in distinct scientific traditions. Land cover refers to the biophysical attributes of the earth's surface and immediate subsurface. This includes vegetative layers (both natural and artificial), exposed soil or rock, water and ice, as well as artificial structures, such as buildings and pavement. While some land covers are considered pristine or at least minimally touched by human use (e.g., remote tropical rain forests), others are recognized as transformed or radically altered (e.g., urban areas). Land use, meanwhile, refers to the human intent to which the land surface is put, and the actions taken to achieve that intent. While use registers as an imprint on a given location in terms of the change in land cover that would otherwise exist, it also includes the motivations, constraints, and enabling conditions that give rise to the use. Land cover and land use each imply both states and processes, and have multiple and overlapping properties.

Because of the compound nature of the questions relating land-use practices to land-cover states and changes, addressing them involves an amalgam of analytical perspectives spanning, for example, the social and physical sciences, quantitative and qualitative approaches, and academic and policy concerns. Each of the research traditions involved brings its own theoretical perspectives and modes of inquiry, and their coupling is not always easy. In particular, the need to merge locally specific explanations of how and why people use land in certain ways with broader patterns observed at regional or global scales brings into sharp relief a long-standing conundrum of scientific inquiry – scale dependence: the dynamics of land change vary depending on the spatial and temporal scale at which they are observed (Easterling and Kok (2002); *see* Scale in Geography). Nevertheless, the enterprise is bound together by the desire to understand how biophysical conditions, particularly 'initial' land cover, shape human activities (opportunities and constraints), and how these activities, or land uses, alter those preexisting conditions, thereby shaping future social and ecological possibilities, as well as the feedbacks, thresholds, and other attributes of such complex systems.

Origins and Motivations of Land Change Science

The relationship between humans and the natural world appears to be a universal concern of Western thought, occupying a central place in Greco-Roman, Arab, and European mythology and philosophy. Modern attempts to characterize the impact of human activities on the earth include George Perkins Marsh's seminal work *Man and Nature* (1864), and multidisciplinary efforts such as *Man's Role in Changing the Face of the Earth* (Thomas, 1956) and *The Earth as Transformed by Human Action* (Turner et al., 1990). More recently, the Millennium Ecosystem Assessment (UNEP, n.d.) sought, inter alia, to quantify the impact of land use on the delivery of ecosystems goods and services. The coalescence of the field of land change science owes much to the development of earth system science over the two past decades, reflecting a growing appreciation for the key role of land change in biogeochemical cycles. At the same time, attention has increasingly focused on the consequences of global environmental change in terms of the sustainability of livelihood systems, of the vulnerability of particular groups of people and places, and of the societal perceptions of and responses to change (Kasperson et al., 1995). These concerns require understanding the human systems – economic, political, cultural, and sociotechnical – associated with human activities at particular places and times (Moran, 2000). Other important questions driving land change research concern the loss of biological diversity through the destruction of habitat and the issue of land rights in the global competition for increasingly scarce land-based resources required to feed rapidly growing demand for food, fuel, and industrial inputs (Foley et al., 2011) .

These concerns are of more than academic interest; policy is actively being crafted to limit human impacts on the environment at both regional and global scales. Many of these policies focus squarely on land use, such as the reducing emissions from deforestation and forest degradation (REDD+) mechanism, which is intended to limit carbon emissions that occur

when forest is converted to agricultural or other uses. The effectiveness of such international environmental agreements depends on sound scientific understanding of the impact of land use, in order to target critical areas and to monitor compliance. Accordingly, research programs have been developed at national and international levels, including the Global Land Project (globallandproject.org), under the aegis of the International Geosphere-Biosphere Programme and the International Human Dimensions Programme (GLP, 2005). Land change research constitutes a bridge between the understanding of the biophysical aspects of global change and the human dimensions of sustainability (*see* Sustainability and Sustainability Science).

Two fundamental, linked, sets of questions underlie land change research: the first concerns the nature, location, and rates of anthropogenic modification of land cover; while the second seeks to understand the reasons behind land-use practices leading to such modifications. The first set of questions is generally examined at relatively broad scales, often using satellite imagery to determine spatial and temporal patterns of change, while the explanation of land-use practices generally requires local scale research, and often involves interviews with land managers and direct observation of land management practices. As answers to these two sets of questions take shape, it becomes possible to model the trajectories of change that have been observed, and to project future land cover outcomes. The following sections treat these issues in more detail.

Land-Cover Dynamics

Our understanding of land-cover dynamics has advanced rapidly over the past two decades, through technological and methodological advances in our ability to observe the current state of the earth's surface from space, and to reconstruct past land-cover patterns with paleological techniques.

Remote sensing of the earth refers to the use of instruments carried on aircraft and earth-orbiting satellites that detect energy reflected or emitted from the earth's surface in different portions of the electromagnetic spectrum. The land cover of most inhabited portions of the earth has been periodically recorded through aerial photography since the 1950s, facilitating the production of land-cover maps. Since the 1970s, satellite remote sensing data have provided more frequent views of large areas (*see* Remote Sensing; Geographic Information Systems; Geographic Information Systems and Remote Sensing).

Land-cover research has utilized three sets of satellite imagery, though the distinction between them is disappearing. One set of satellite instruments (e.g., those carried on the Landsat, SPOT, and ERS platforms) provides relatively high spatial resolution, sampling the earth's surface on the order of tens of meters, along swathes of 100–200 km. While such imagery is capable of distinguishing several types of land cover at scales closely corresponding to the case studies needed to understand land use, these satellites take weeks to observe the entire surface of the earth, and views of land-cover are often inhibited by cloud cover or other atmospheric conditions, especially in the tropics.

Other satellite systems, originally intended for the observation of weather, acquire daily views of the earth. Short series of these daily views may be combined to create cloud-free composite images for weekly or monthly intervals. These data sources previously suffered from very limited spectral and spatial resolution, but still yielded valuable information on seasonal and longer-term climatic patterns, such as the El Niño Southern Oscillation. More recently, daily imagery is being acquired by sensors with improved spatial and spectral resolution (e.g., NASA's MODIS instrument), further enhancing the ability to detect temporal patterns. These data have helped to support the rapidly growing field of phenological analysis, separating the background of natural cycles and rhythms to more reliably detect anthropogenic land-cover change.

Over the past decade, a third set of imagery has become widely available, mainly through private sector satellite systems, offering very fine-grained views of the earth's surface once available only to the defense/military intelligence community. These commercial systems deliver imagery with pixels corresponding to less than 10 m, and even less than 1 m, on the ground. Concurrent advances in computing power and storage capacity have made the analysis of such imagery for small areas feasible for even moderately equipped laboratories or individuals.

As the data from the various satellite systems are better integrated, the gap will close between the global coverage and local case studies using aerial photography and high-resolution imagery. Attempts at such integration have highlighted the disparities between analytical schemes for characterizing land cover, as well as the difficulties of merging information about biophysical and social dimensions of land change (Rindfuss et al., 2004).

In addition to the very detailed record of land-use and related land-cover impacts provided by remote sensing over the second half of the twentieth century, our knowledge of prior land-use impacts is also growing through the analysis of pollen in sediment cores and other paleoecological and archaeological techniques. Such techniques have enabled the estimation of the earth's land cover 6000 years ago (GAIM, 2000), and detailed reconstructions have been made for the past three centuries by projecting current land cover back in time using historical agricultural and demographic information (Klein-Goldeweik, 2001; Ramankutty and Foley, 1999). The convergence of remotely sensed and other historical sources with prehistoric reconstructions will provide a much fuller picture of the earth's land cover throughout the anthropocene (Crutzen and Stoermer, 2000), yielding valuable insights on long-term trajectories of change, and of possible path dependency in the evolution of regional land-cover patterns (*see* Anthropocene Epoch).

Land-Use Dynamics

Elements of land-use practices have been a staple topic of investigation for numerous disciplines in the social sciences, including anthropology, archaeology, demography, economics, geography, history, political science, and sociology. Through different lenses, scholars in these fields have sought to explain how and why people in different parts of the world have

developed technology and social systems in response to local environmental conditions, how these human actions have, in turn, shaped the local environment, and how people subsequently respond to these changing conditions (Redman, 1999). Thousands of case studies have been undertaken, usually concerning communities or small regions, and efforts are increasingly being made to synthesize these cases in order to extract general principles and to develop a unified theory. While the history of land use in Europe is well documented, land-cover transformation has been perceived to be most dramatic in the tropics in recent years, and a great deal of attention has been accorded these regions, with particular attention to agricultural 'land grabs' (Lambin and Meyfroidt, 2011).

A broad range of factors has been proffered to explain local land-use practices, with perhaps the greatest effort spent examining agricultural change and the role of population growth (*see* Agroecology and Agricultural Change). The now-famous work of British economist Thomas Malthus, who predicted famine as an inevitable result of population growth in Europe, has fostered huge debate within the social sciences. Another major landmark was the work of Ester Boserup 1965[1993], who turned the Malthusian thesis on its head, attributing agricultural development in Asia to land pressure driven by population growth. Subsequent refinements have described a range of land-use change trajectories that may emerge from land pressure and suggested how the driving forces of change are mediated by social and environmental factors at many levels (Roy Chowdhury and Turner, 2006).

In addressing the relationship between population growth and land degradation, political economic analyses hold external forces responsible when land managers engage in environmentally destructive land-use practices. Likewise, cases have been articulated of population growth leading to the rehabilitation of natural resources, including afforestation. A great deal of work has been done to examine the role of demographic factors in land use change, with particular emphasis on government-subsidized settlement programs in Latin America, and rural–urban migration in Africa and Asia. Results suggest complex relationships between land-cover dynamics and the provision of infrastructure (especially roads), family development cycles, urban wage employment, and other factors that vary strongly by region (e.g., Lambin and Geist (2006); *see* Property Rights).

n the case of forest cover, global scale empirical evidence reveals a complex relationship between forest cover and population density, suggesting that as population density rises in newly settled regions, forest cover has often been removed for the purposes of agricultural expansion. Another period ensues during which wood fuel is replaced by other sources (e.g., fossil fuels) and agricultural intensification allows for the production of sufficient food on less land. Eventually affluence rises to the point where attention to environmental rehabilitation becomes feasible and afforestation becomes the dominant trend, in what has become known as the forest transition (Rudel et al., 2005).

In order to synthesize the findings of the hundreds of cases, studies in the peer-reviewed literature, a number of *meta*-studies have been conducted on the processes of deforestation (Geist and Lambin, 2002), desertification (Geist and Lambin, 2005), and agricultural intensification (Keys and McConnell, 2005).

Land Change Models

Perhaps the main challenge of land change science is to forge robust linkages between the broad views of land-cover change provided by remote sensing and other techniques, and the fine-grained understanding of land-use dynamics. In weaving these together, land change modeling examines the observed paths, or trajectories, and often projects them into the future. While this may not always lead to prediction, it can suggest what might happen should present trends continue and, perhaps more importantly, suggest other possible futures. There are significant obstacles to achieving this integration of land-use and land-cover perspectives, but advances in geographic information technologies and new analytical techniques are enabling significant advances (see Spatial Analysis in Geography).

Most early models of land-cover change were either empirical (mimicking the observed relationships between variables, such as forest cover and population density), or mechanistic (describing a limited range of landscape processes according to simple equations) (Kaimowitz and Angelsen, 1998). While such models have the advantage of requiring minimal empirical evidence (e.g., maps of forest cover and population density), their utility is limited by the assumptions that such relationships will persist, and that they are the main determinants of land change (Lambin, 1994). However, it is increasingly recognized that these conditions (particularly in the socioeconomic realm) are mutable, requiring consideration of alternate scenarios outside the empirical record (Aspinall, 2004). In order to incorporate the information gleaned through research on land-use dynamics more realistically, a new generation of dynamic simulation models has undergone rapid development over the past decade that model the behavior – and even the learning processes – of individual actors, or agents, in the landscape (Parker et al., 2003; *see* Agent-Based Modeling and Associated Statistical Aspects).

Summary and Outlook

Land change science is an inherently interdisciplinary field of inquiry, bringing to bear a broad range of perspectives to explicate and model the highly complex interplay of human and natural forces shaping the transformation of the earth's surface. The maturation of the field over the last decade has been marked by its burgeoning breadth of experience and deepening responsibility to the challenge of sustainability. The increasing proliferation of case studies will continue to engender more sophisticated and innovative synthesis efforts, building on developments in *meta*-study techniques across the disciplines (Magliocca et al., 2014; *see* Sustainability and Sustainability Science). These syntheses will benefit from the trend toward the use of continuous variables in case studies, describing both the land change outcomes and the factors involved in creating them in finer detail. Developments in the field will be driven by societal needs to manage the flow of ecosystem goods and services, with accounting for carbon stocks, for example, now crucial to the enforcement of international environmental agreements (e.g., REDD+) and to financial instruments (e.g., carbon credits) intended to stabilize

the earth's atmosphere. Technological advancement will continue to occur both in the availability of historic (i.e., declassified) and contemporary (especially private sector) remotely sensed imagery, as well as through more powerful computing hardware and software, with broad-ranging high-speed Internet access giving virtually anyone the tools needed to detect, describe, and explain changes in the landscape. Together, these advances will contribute to the development of increasingly robust theoretical understanding of this crucial aspect of human–nature interaction.

Abstract

Geography, as a modern scholarly discipline, has its roots in the European Renaissance and Enlightenment rediscovery, and rethinking, of the ancient Greco-Roman classics. Though the word landscape is of Germanic origin, its use in geography must be understood in this cosmopolitan disciplinary context, and notably in relation to the key ancient Greek geographical concept of *choros*, meaning 'land,' as the 'land' in landscape. There are two classical paradigms for landscape study: one exemplified by the narrative, humanities-oriented approaches of Herodotus and Strabo, and the other deriving from the mathematical and scientific approach of the geometer, cartographer, geographer, and astrologer Claudius Ptolemy. This article will trace the entangled history of the two as they manifested themselves in diverging ideas of landscape as a meta-disciplinary concept.

Introduction

The Greek Herodotus (*c*.484–425 BC), who helped found history, ethnography, and geography as interlinked studies, and for the latter Greco-Roman geographer Strabo (64/63 BC–*c*.AD 24), *choros* (*also spelled chora and khora*) referred to a particular place, country, or 'land,' with its language and customary laws – e.g., a Greek city-state. *Chorography* meant the largely narrative written description (*-graphy* meaning writing) of a historically constituted land/country, or *choros*. Cartographic representation, by contrast, was foundational to the Alexandrian Greco-Roman geometer, geographer, and astrologer Claudius Ptolemy's (*c*.AD 100–178) conception of geography. Rediscovered in the Renaissance, his geography was promoted by Enlightenment scientists such as Britain's Isaac Newton (1643–1727) and Germany's Bernhardus Varenius (1622–50), as a template upon which modern scientific geography subsequently was significantly built (Warntz, 1989; Martin and James, 1993).

For Ptolemy, 'geography' literally was the graphic science of locating earthly positions on the surface of a globe according to celestial coordinates, whereas 'chorography' involved the demarcation of areas on the globe. For him, as a cartographer, '-graphy' meant imitation/representation through a graphic form, which in the Renaissance was interpreted to mean cosmographic 'pictorial form' (Olwig, 2008). Ptolemy wrote

> Geography looks at the position rather than the quality, noting the relation of distances everywhere. [.] Chorography needs an artist, and no one presents it rightly unless he is an artist. […] In Geography one must contemplate the extent of the entire earth, as well as its shape, and its position under the heavens. […I]n short all things having regard to our earthly habitation.
>
> Ptolemy, 1991, p. 26

Ptolemy's approach reconfigured *choros* in terms of a mathematical, scientific (and astrologic) logic suitable to Roman imperial governance (van Paassen, 1957). A Ptolemaic globe, the prototype for modern cartography, is made by creating a geometric framework of lines of latitude and longitude and then situating locations within it using celestial astronomical observations. Cartographic maps are made by projecting this global space onto the two-dimensional, gridded, and scaled space of a 'graticule' drawn upon a flat and usually square surface. Because, according to Euclidean geometry, lines and points in space are ideal adjuncts to thought found nowhere on terrestrial earth (and are hence utopian), a line has no width and a point no circumference. There is thus no theoretical limit to the points of location that can be plotted on the lines crossing the map's gridded graticule, and there will therefore always be space between them. To demarcate an area on a globe or map one must thus, for both practical and theoretical reasons, connect the dots of the plotted positions, filling in the space between them using the graphic skill, or 'art' of an artist in the archaic sense of an artisan, to create an outline of an area. This activity involves a process of skillful translation from the infinite geometrical integers of a gridded, ideal, Euclidean space, to a finite shape that is analog with a continuous physical terrestrial phenomenon, such as a shoreline. The same skill was required for topographic mapping (**Figure 1**). Today's standard dictionaries continue to define chorography in terms of the art of cartographically defining regions and places, i.e., as: "the art of describing or mapping a region or district," and topography as "the art or practice of graphic delineation in detail usually on maps or charts of natural and man-made features of a place or region especially in a way to show their relative positions and elevations" (Merriam-Webster, 1996: chorography, topography). Through such mapping processes the meaning of *choros* and *topos* underwent a critical change from being a historically and socially constituted land and place, to a technique of representation within a fixed and unchanging ideal geometric space. This technique was useful not only for astrology, but also for commercial and military purposes, as when navigating across an open sea, and for predicting the general location of climate belts, the supposed racial characteristics of peoples that are determined by living in such environs, and other natural phenomena. The technique was therefore vital to the dawning age of world exploration and it was duly embraced by the inheritors of Enlightenment science (Livingstone, 1992). It also made possible the contemporary spatial enclosure of places, so that common lands belonging to political communities with use rights to the material properties of their varied places (*topos*) could be transformed into private properties enclosed as land surface within the Euclidean,

Figure 1 Ptolemy's division of geography into geography proper, chorography, and topography, from Peter Apianus, *Cosmographia* (Antwerp, 1540). The globe of the earth represents geography proper, the chorographic regions of the earth, top right, are analogous to the face.

chorographic space of a cadastral map. This, in turn, facilitated the buying, selling, and agricultural specialization of land as a physical area of property, and thus the transition from a feudal to a modern exchange money economy (Cosgrove, 1984).

The Meanings of Landscape

A landscape was originally, in the Germanic languages, including English, a place (in the original sense of *choros*) having, like a Greek city-state, the character of a country or land, but usually subordinate to a greater authority, as in the Netherlands' federation (Olwig, 2002). The word *pays*, as in *paysage*, likewise meant land as a country, but unlike in the Germanic languages, it could not be confused with land surface, soil, or terrain. The suffix '-scape' in landscape is equivalent to '-ship,' meaning, among other things, 'character,' 'shape,' or 'constitution' as in *friendship* (the characteristic quality shared by friends constituting friendship) (Merriam-Webster, 1996: landscape, -ship). The suffix '*-age*' in the French *paysage* in the Romance languages has the same meaning. A sixteenth-century painting of a landscape polity making up the Dutch federation would seek to capture its '-ship,' character, shape, or constitution as a land – something of political importance due to the imperial, centralizing, threat of Spain. Landscape painting, in origin, thus involved portraiture of the people, customs and history of a land comparable to written depictions of places or lands in contemporary chorography. The pan-European popularity of Netherlands' landscape paintings led to landscape's establishment as an artistic genre alongside portraiture and history painting. But just as Ptolemaic cartography transformed the meaning of chorography, turning it into a form of cartographic representation, the techniques of Ptolemaic cartography changed the meaning of landscape when they were applied to the visual portraiture of landscape.

The Renaissance rediscovery of Ptolemaic cartography provided a basis for the development of pictorial perspective within a spatial framework inspired, at least in part, by Ptolemaic chorography and topography (Cosgrove, 1984). As noted, Ptolemy's notion of the '-graphy' in chorography was interpreted in the Renaissance as referring to a 'pictorial' form of representation involving art, and this idea helped spur the use of spatial perspectival techniques derived from Ptolemaic mapping to create artistic representations in,

for example, landscape painting and theater scenography (Olwig, 2002, 2008). This was done, simply put, by changing the angle of projection from top-down to more horizontal. This scenic representation required a reconfiguration of the grid used to plot cartographic locations, so that its lines no longer form rectangular shapes, but rather appear to taper inward toward an infinite vanishing point. Art is then used to plot and delineate a perspectival scene by connecting points within this ideal spatial framework to form recognizable shapes. As the eye is drawn inward to the point of infinity an illusion of gradually changing scalar depth is created on the flat surface (**Figure 2**).

Just as there is a discontinuity between locational points plotted upon a graticule of a chorographic map, there is also a discontinuous break between chorographic areas plotted upon maps of different scales. Scale derives from *scala*, the Latin for ladder, and this discontinuity is comparable to the break between the rungs of a ladder. The same problem of discontinuity also arises when demarcating topographical layers on a topographical map, so that mountains, for example, are not represented with smooth sides, but appear more like a wedding cake seen from above. It nevertheless proved possible to create an illusion of gradually changing spatial depth through the use of spatial perspective, thereby smoothing the discontinuities of scale. The same problem of discontinuity applies to temporal scale, so that no matter how many historical maps one might make of differing periods in an area's history, there will always be a temporal gap between them, meaning that one must surmise, using the art of the historian, what has happened between each mapped layer of history (Darby, 1962). The use of spatial perspective in theater scenery, however, made it possible to create a realistic illusion of temporal change occurring within the unified time and space of the theater (Olwig, 2002).

The application of central point perspectival techniques to depictions of landscapes had the same effect as the application of Ptolemaic geography to chorography. Landscape thus underwent a similar critical change from being an historically and socially constituted land and place, to being first a form of representation, and then the world understood as scenery, as perceived in such a representation (Cosgrove, 1984). Especially in Italy, these techniques were often used to depict ideal landscape scenes inspired by Biblical and mythical Greco-Roman stories, rather than actual mundane places, as in the Netherlands. The term landscape could thus now be used to refer not to an existing place, but to a form of spatial representation, as well as subject matter perceived in such representations, so that landscape became synonymous with scenery or terrain per se. It thereby became a universalized form of representation applicable to any phenomena, including scientific models of natural processes. However, just as a change in the projection of a map creates significantly different images of the world, so too do changes in the projection of a perspectival representation. The scientific objectivity of a map (and its scale) and perspectival depiction are thus somewhat illusory – a matter of 'point of view.'

Like the Ptolemaic map, the perspectival representation of *choros* as landscape scenery had implications for science. Already in the sixteenth century it had become common to name Ptolemaic Atlases 'theaters,' as with Abraham Ortelius' *Theatrum Orbis Terrarum* (*Theater of the Lands of the World*) (Ortelius, 1595 (orig.) 1570), and they typically included both top-down and more horizontal views, resembling the world as seen as the scenery on the then newly invented perspectival theater stage (**Figure 3**). Prophets of modern science, such as Bernard le Bovier de Fontenelle (1657–1757) and Antoine-Nicolas De Condorcet (1743–94), envisioned science in terms of a theater stage, upon which temporal scientific and social progress occurs in changing historical stages, as in a theatrical drama (Olwig, 2002). The perspectival scenery on the stage floor thus represented the land surface, soil, and geological/topographical shape of a land (still described as 'scenery' in some modern geology texts), and the stage scenery upon it represented the flora, fauna, and cultural features of the land, whereas climate was located in the area above stage. This form of representation allows for a shift in the meaning of land from the place or *choros* of a polity (e.g., Scotland) to simply soil (e.g., wetland). Landscape could thereby be stripped of its link to social phenomena, and become a 'physical' or natural phenomenon, to be studied by natural scientists, or it could represent a synthesis of physical and cultural landscapes, illustrating the interaction between society, flora and fauna, geology, and climate (**Figure 4**).

Alexander von Humboldt (1769–1859), one of the most famous and widely read scientists of his time, is often regarded as a founder of modern geography (Martin and James, 1993). His

Figure 2 Illustration from Albrecht Dürer, *Underweyssung der Messung* (Nuremberg, 1538). The male draughtsman is using the techniques of cartographic surveying to create an illusion of three dimensional, bodily space, as represented by a woman, but also by the landscape scene seen through the window, and, in a circular way, the entire drawing, which itself is done in perspective.

Figure 3 This plate from Ortelius' late sixteenth-century Atlas, *Theater of the Lands of the World*, illustrates how a more perspectival and horizontal view of the world merged with a more top-down cartographic representation of a region.

success owed in part to his understanding of the value of landscape, together with cartography, chorography, and topography, as a means of studying, explicating, and popularizing natural history. Traveling the globe Humboldt was able to map and correlate physical and cultural geographical phenomena according to the chorographic and the scenic structure of landscape. He thereby became a founding figure in fields such as climatology, oceanology, and plant geography, while using landscape artists to capture and communicate the visual character of places. Humboldt, furthermore, was not blind to the importance of the more literary tradition of Herodotus and Strabo, writing:

> In classical antiquity the earliest historians made little attempt to separate the description of lands from the narration of events the scene of which was in the areas described. For a long time physical geography and history appear attractively intermingled.
>
> von Humboldt quoted by Sauer, 1969, orig. 1925

Humboldt's writings, in turn, inspired the young Charles Darwin to undertake his voyage with the Beagle (Livingstone, 1992). Darwin's resultant theory of evolution then charted the developmental stages of life itself in terms of an interaction between species and their landscape environment. Landscape was thus not so much a subject of particular study, as a metastructure, embodying chorography, topography, cartography, and cosmography, which was used to organize and transmit knowledge, embodying an entire cosmology as outlined in Humboldt's seminal *Cosmos: A Sketch of a Physical Description of the Universe* (Humboldt, 1849–58).

By the beginning of the nineteenth century most European states had developed a centralized government within relatively clear chorographically mapped boundaries, encompassing a relatively unified people speaking a national language (Tang, 2008). This was not the case for Germany, which was divided into a myriad of polities ranging from large kingdoms, such as Prussia, to small landscape polities (*Landschaft*), wherein mutually unintelligible German dialects often were spoken. Groups of German-speaking people were also dispersed across especially Eastern Europe, often in isolated enclaves. The nineteenth century was a time of European nation-state building, and it was especially in Germany that a geographical discipline was needed, especially in the schools, to help make sense of Germany as a nation in the world. Landscape, with its ability to unite chorography, topography, and cartographic spatial relations, played a particularly important role in this, at a time when German landscape art also flowered. This might explain why, during the nineteenth century, German geography dominated the discipline internationally, starting with Humboldt, and why landscape played such an important role in that geography. Toward the turn of the twentieth century, when geography became formalized as a university discipline, the subject was therefore layered into differing areas of specialized study within the physical and/or human sciences which, when linked together, could be seen to form an overarching, metatheoretical, physical, and cultural landscape totality. Thus, in 1925 when Carl Sauer was founding the new geography department at the University of California, Berkeley, he laid the department's groundwork with a magisterial survey of Western geography, dominated by German geographers, entitled *The Morphology of Landscape* (Sauer, 1969).

Figure 4 Thomas Hobbes' pioneering 1651 work on the constitution of the state in terms of its matter, form and power used a perspectival image of a landscape as commanded by the vision of the head of state.

The Collapse of Landscape's Disciplinary Hegemony

Geography is still divided into physical and human sections, reflecting the division between the physical and the cultural landscape within an overarching landscape totality, but this structure has become increasingly strained since World War II. Particularly Germany's ideological excesses led many non-German geographers to question the German foundations of their field.

The idea that the space inhabited by a nation should be demarcated within the chorographic space of map was, as noted, foundational to the nation-state. The post-Darwinian landscape paradigm suggested an interaction between this national space's physical landscape and its cultural landscape, changing in stages through time in a process of evolution according to the geographical doctrine of 'environmental determinism.' This interaction was foundational to nationalist *Blut und Boden* (German for 'blood and soil') ideology, which contended that the character of the human races developing within the national territory was determined by their historical interaction with the national natural environment, and which argued for the maintenance of national racial purity through the exclusion of non-German nationality, especially those deemed to be racially inferior. This same ideology suggested that superior national races would 'naturally,' according to evolutionary doctrine, grow and expand, and therefore need *Lebensraum* or 'living space' – a relational space with disastrous consequences for the peoples whose lands the Nazis sought to colonize. These ideologies, however, were by no means exclusive to the Germans; they were also used to justify imperial expansion by other nations. As an ideal model the interaction of environmental factors within the chorographic space of landscape was heuristically useful for the development of evolutionary theory, especially as an island in the Galapagos presented a neatly bounded chorographic space. But the German state could not be comprehended as a large-scale chorographic island. Landscape art created a perspectival illusion of a unified national space, and chorography provided a means of mapping that space. This space and its boundaries, however, were illusory and utopian, and could not be applied, without becoming dystopian, to an area made up of a large number of heterogeneous territories with varying histories, populations, languages, and religions, and its borderland areas of mixed nationalities.

Landscape in Post-World War II Geography

Nationalist ideological excesses led to a questioning of the discipline's established paradigm. A leading figure in the post-war revisioning of geography was Richard Hartshorne, an American who, among other things, sought to cleanse geography of landscape. Hartshorne had studied in Germany and his approach to geography was grounded in German ideas of science, or *Wissenshaft*, and geographical theory, particularly the 'chorology' of Alfred Hettner. *Wissenshaft* was a broad notion of science in which the rigor of the natural sciences was also sought brought to bear on social phenomena, thereby ostensibly creating objective knowledge. From this perspective the nationalistic ideological excesses owed to a misuse of objective science for subjective ideological purposes, and it would thus be possible to avoid ideological misuse through rigorous *Wissenshaft*. Hartshorne's solution, following this logic, was to retain the *chorographic* approach, but transform it from a descriptive graphic study to an empirical 'spatial' science concerned with regional study. Hartshorne's chorology would be devoted to the correlation of a diversity of data within areas demarcated by the geographer according to analytical, rather than historical, criteria. This was to be an 'idiographic' approach concerned with specific facts or processes occurring in unique places, as distinct from generalizable (nomothetic) laws (Hartshorne, 1939), thus preventing the formulation of causal laws, applicable anywhere, such as those of environmental determinism, *Blut und Boden*, or *Lebensraum*. Hartshorne's chorology excluded the study of landscape with its concern for the historical interaction of society and its environment in a given historically constituted area. In English, he further argued, landscape meant a scenic phenomenon, perceived as extending into infinity, not a bounded area, as in the German language and in German geography. Hartshorne's redefinition of geography suited his own personal interest in economic geography, and hence geography as basically a social science, rather than

an environmental science. Hartshorne became the leading theoretician of mainstream geography in the post-war English-speaking world (Hartshorne, 1959), but his focus on chorology was eventually eclipsed. This happened largely in the 1960s through a shift to the nomothetic study of spatial location in the tradition of Ptolemy's idea of geography as a locational science. By this time spatial science's own Nazi past had been forgotten (Rössler, 1989), and it was largely believed, furthermore, that 'objective' positivistic science, like *Wissenschaft*, would be a guarantee against ideological misuse. The rise of geography as spatial science thereby marginalized landscape as a paradigmatic framework for mainstream English language geography. This was not the case, however, with geography in Germany. In many continental European countries within the sphere of influence of traditional German geography, where rigorous *Wissenschaft* was believed to mitigate ideological misuse, the traditional German approach to landscape, combining the study of the physical and cultural landscape through time, remained important and contributed to the subsequent development of landscape ecology. The notion of landscape, however, took a very different turn with regard to the geography emanating from Berkeley under the stewardship of Sauer. Here, landscape developed along a different path from either geography as the science of space, or traditional German landscape geography.

The Berkeley School Landscape Studies

The critique of landscape mounted by Hartshorne did not fit the approach to landscape taken in practice by Sauer and his colleagues and students as they developed it over time (Sauer, 1969; Denevan and Mathewson, 2009). The reason is that Berkeley geography followed an interdisciplinary humanities-oriented approach more in the vein of *choros* (which he spelled *chore*) as understood by Herodotus and Strabo, than Ptolemy's chorography, which they criticized. Sauer's landscape geography was thus wedded to the study of history, anthropology, archaeology, and place, even if it included a concern with natural science and cartography. Sauer severely criticized environmental determinism and focused upon human agency in shaping differing landscapes, viewing landscape as a mental, social, and physical 'phenomenon.' The conference and book, *Man's Role in Changing the Face of the Earth*, gives a good impression of the breadth, depth, and impact of the 'Berkeley school' and its British counterpart in the school of H.C. Darby's historical geography (Thomas, 1956). Landscape geography, nevertheless, led a subaltern existence within a discipline increasingly dominated by various permutations of spatial social science. A new approach to landscape geography, however, did develop in the interstices between Berkeley geography and spatial science.

Landscape Perception

During the 1960s David Lowenthal, a geographer and historian who had studied both at Berkeley and with Hartshorne at the University of Wisconsin, effectively turned Hartshorne's critique of landscape on end. Sauer had defined the study of landscape in 'phenomenological' terms, meaning that landscape was not constituted analytically through science, but was rather, following Sauer, a 'phenomenon' that was perceived as a basic epistemological category by laymen. Lowenthal took this idea and applied it to Hartshorne's understanding of landscape as a scenic perception of the environment. Lowenthal argued that the study of ordinary people's environmental perceptions was necessary if geographers wished to understand human attitudes and behavior (Lowenthal, 1961). Similar approaches were taken at this time by humanities-oriented American geographers with an affiliation to Berkeley, such as Yi-Fu Tuan and J.B. Jackson, thus helping to generate a subfield concerned with the perception of landscape and the environment. At this time landscape, conceptualized largely as scenery, became an object of public management in nature conservation, cultural heritage, agricultural policy, and physical planning. The British geographer Jay Appleton, working in this context, combined the landscape perception approach with evolutionary biology, arguing that the frequent use of a dark foreground in landscape painting reflected 'man's' prehistory as hunters seeking 'refuge' in the shadows where they looked out over a landscape 'prospect' while stalking game (Appleton, 1975).

Appleton's return to a variant of Darwinian environmentalism sparked a counterreaction among some British geographers, notably Denis Cosgrove, with a more humanities-based and social constructionist orientation. Cosgrove argued that the perception of landscape in scenic terms as prospect was not an outcome of evolutionary biology, but rather of the Renaissance development of the techniques of perspectival representation. Focusing on Venice, he saw a vital connection between the rediscovery of Ptolemaic cartography, the surveying practices of land drainage and enclosure, the development of landscape architecture, and the ability to understand, appreciate, and transform the world as perspectival spatial scenery – an approach to landscape that jibed well with geography conceptualized as spatial science (Cosgrove, 1984). Working with Stephen Daniels, who took an art and gardening history perspective, and the Canadian-British geographer James Duncan, who applied a semiotic perspective, Cosgrove pioneered an approach, influential well beyond the bounds of geography, defining landscape principally as a form of visual representation (Cosgrove and Daniels, 1988).

For Cosgrove, the concept of landscape originated with perspectival representation through which people learned not only to perceive the world as landscape scenery, but also to shape it as landscape scenery, as in landscape architecture. This analysis, however, did not take into account that landscape existed as place and polity (*choros*), prior to its representation in perspectival space, and that it still was regarded this way in many areas of Europe, particularly in the Nordic region (Olwig, 2002; Jones and Olwig, 2008). This shortcoming does not mean that the scenic, perspectival, reconceptualization of landscape as space has no importance, but it makes it necessary to understand the substantive relationship between the way places conceptualized in terms of the older sense of landscape are socially and legally constituted, and governed, in terms of, for example, customary use rights to commons rather than property rights to enclosed land, or the governance of federated polities rather than that of a centralized state (Olwig, 2002; Cosgrove, 2004). The substantive approach to landscape has helped ameliorate French philosophy-inspired criticism of the visual bias in landscape studies (Jay, 1994), as well as critique

by those who see landscape as the embodiment of practice and labor (Ingold, 2000; Mitchell, 1996), or who are inspired by nonrepresentational geographical theory (Wylie, 2007).

Conclusion

Landscape has played a prominent role in geography as an overarching metaconcept through which the character, shape, and constitution of a land, understood as *choros*, has been understood. In one sense it has been perceived, in the tradition of Herodotus and Strabo, as the interlinked object of historical, ethnographical, and geographical narrative closely linked to the humanities. In another sense, it has been defined as a mode of scientific spatial representation encompassing cartographic chorography, topography, cosmography, and geography as a locational spatial science, and the scenic phenomena thus represented. The two senses, overlapping through time, have not just provided a framework for geographical study, but also a medium through which people in society have comprehended, for example, their place as commoners in a landscape polity, or as private property owners and citizens of a nation-state. This is evidenced today by the European Landscape Convention, as promulgated by the Council of Europe and ratified by most European states, which defines landscape as "an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors." It calls for states "to recognise landscapes in law as an essential component of people's surroundings, an expression of the diversity of their shared cultural and natural heritage, and a foundation of their identity" (Europe, 2000). The Convention, in turn, has stimulated recent scholarly interest in the link between landscape, human rights, and democracy (Egoz et al., 2011; Jones and Stenseke, 2011). Landscape thus continues to be of relevance to geographers, and to society at large, even if its meaning has changed through time, resulting in an entangled complex concept that is as good to think 'with,' as 'about,' because the transformations of its meaning over time and space reflect the historical transformations of society and its geography.

Land Tenure

Abstract

Land tenure, connecting to much-debated issues of human territoriality and sovereignty, can be approached at any level of scale from domestic to cosmic. As presented in this article, land tenure moves beyond the confines of conventional English legal terms like 'rights and duties' and political–economic ones like public or private 'property,' or collective or individual 'ownership.' A wider array of concepts, taking real access, attachment, and mobility into account, is needed to capture the new practices and institutions for recording land-use patterns that arise locally or are produced by diverse directed tenure reforms. Particularly in postauthoritarian settings, land property claims are becoming central in continuing struggles over belonging and identity. New forms of decollectivization as well as intensifying land grabbing for agri industries produce novel patterns of exclusion and debates over territory and jurisdiction. Where migration is concerned, and where persons absent as well as present can make land claims, scholars and practitioners alike encounter yet unstudied forms of tenure. Terms and translations – for people, things, and links between – are critical throughout.

Introduction: Struggles Over Land and Meaning

Land can refer to space or place, often denoting material substance deemed immovable, and sometimes connoting belonging. In some tongues, it takes several distinct words to translate, and corresponding terms may or may not include water, plants, animals, people, and built or dugout structures. 'Tenure' (from L. *tenere*, to hold) or landholding need not refer just to a particular form of legal, political, or economic regime (such as freehold, fiefhold, or collective village ownership) but can indicate human–land attachment in a broader sense, taking account of unofficial, illegal, or occasional use, and of persons living, dead, or unborn.

"Nearly all social struggles in Antiquity," claimed Max Weber, "were essentially for the ownership and use of land" (1988, p. 343). He might say the same for recent times. Particular regions have hallmark forms of land tension and strife, simplified and sharpened in mass media if not also in scholarly representation. Such are ethnoreligious struggles over autochthony in the Levant and Northern Ireland; forced transmigration in Indonesia; latifundio, minifundio, squatting, and private militias ('goon' squads) in Hispanic America; small-tribe survival struggles in Amazonia; landlord–tenant exploitation in South Asia; plantation oppression in the Caribbean and island southeast Asia; collectivization and decollectivization in Russia and China and states in their hegemonies; farmer–herder conflicts in the American west or the Sahel; and individual titling that threatens women, children, and the rural poor in the African tropics. But none of these regions monopolizes the tenure issue for which it is famed. Tasks for social scientists and humanists include finding particularities and exceptions, bringing to light indigenous practical solutions, and assessing the performance of authorities that claim jurisdiction or sovereignty.

Historical Background

Records of land claims and transfers have been dug up among some of the earliest known writings in Mesopotamia from 4000 to 5000 years ago, along with royal edicts canceling subjects' debts and reversing land forfeitures to creditors. Plato's and his student Aristotle's debate about the merits of public versus private landholding in the Aegean *polis* echoes two millennia later in European and American traditions. John Locke, Adam Smith, and Herbert Spencer are still widely cited by private property's upholders, while the young Jean-Jacques Rousseau (esp. 1965), Karl Marx, Pierre Proudhon, and (in America) Henry George are champions of its critics.

Evolutionist Political Philosophy

The spread of European imperial power and the westward expansion of Euro-American settlement in the late nineteenth and early twentieth centuries, accompanied as they were by wholesale expropriation or disenfranchisement of foragers, mobile herders, and swidden (slash-and-burn, long fallow) farmers, led sociologists and anthropologists into the study of land tenure as their disciplines coalesced. Jurist Henry Maine's vision of Roman property law's and human history's evolution from ascribed 'status' to achieved 'contract' was qualified by lawyer-anthropologist Lewis Henry Morgan's conclusion in *Ancient Society* (1877) that individual property was an inadequate basis for civilization's further progress. Societies moved, wrote Morgan, from *societas*, i.e., ties based on kinship and other particular ties, to *civitas*, ties based on territorially defined polity, but this did not always mean upward progress either. Karl Marx and Friedrich Engels, inspired by Rousseau and Morgan among others, envisaged history as a one-way flow through stages of prefeudal tribalism, feudalism, capitalism, socialism, and finally a future communism with abolition of private property and state government.

Evolutionist theories based on a largely imaginary prehistory and assumptions of unilinear change continue to resound in legal, political, and economic circles. But twentieth-century anthropology made it more apparent how tenure change can zigzag and backtrack, and how many different forms of tenure can be 'modern' at once, sometimes in close coexistence.

Persons, Things, and Systems

Early ethnography in Australia and Native America, and Bronislaw Malinowski's (1935) work on Trobriand Island gardening in Melanesia in the 1910s, revealed indigenous concepts in which human groups and spaces (however defined)

were deemed aspects of each other, often inextricable from spiritual beings or forces. Research in colonial Africa in the mid-twentieth century depicted how land tenure tied tightly into cognition, language, and translation; kinship and friendship; political control and hegemony; religion and ritual; and esthetics and myth (Meek, 1949; Biebuyck, 1963). Monarchs' and chiefs' control over land (as in Buganda or Ashantiland) appeared to be part and parcel with control over people, but their rights excluded alienation by sale and other rights often identified with ownership. Landholding was justified by clearing, residing on, or working on the land; by conquest; by membership in a kin or local group; by chiefly assignment and tribute; or a mix of these. Multiple rights of different groups to use land for different purposes, for example farming, grazing, and thatch, firewood, or clay collection, overlapped in complex ways not captured by terms like 'property' or 'ownership.' In 'acephalous' (politically uncentralized) societies like those of Tiv in Nigeria or Chagga in Tanzania, land territories were often found closely linked to genealogy of clans or lineages, shifting and stretching as these moved, grew, or shrank. Here and elsewhere in Africa, land was spoken of as an active interest of not only the living, but also the dead and unborn. To Audrey Richards, Lucy Mair, and other British-trained social scientists, land tenure appeared as part of complex, functioning cultural systems. Max Gluckman's southern Africa-based work on 'hierarchies of estates' over land, for instance of use, transfer, and administration, influenced a generation of tenure studies. Gluckman (1965) observed that property is not just about rights of people over things, but also about duties between people with respect to things.

Structure and Process of Inequity: Critical Rethinkings

In the 1960s and early 1970s, Latin American-inspired scholarship on dependency and 'modes of production,' in a Marxist vein, criticized the exploitation of rural and tropical peripheries by metropolitan capitals by agribusiness or plantation owners and through the co-optation of comprador (buyer) elites. South America, the continent with the longest history of European colonialism, had, some observed, the most uneven distribution of landholdings (Orlove and Custred, 1980). Parisian Marxist structuralists in the late 1970s revised the view that capitalism eroded all other forms of tenure and exchange (quasifeudalism, family farm holding, etc.), contending instead that it encapsulated and preserved these for its own profit.

In the 1980s and 1990s, social scientists with political–economic interest turned their attention to attempts by national regimes to monopolize power over land relations, particularly in Africa. State attempts to nationalize, privatize, or socialize landholding now looked like raw or subtle power grabs (Downs and Reyna, 1988; LeBris et al., 1991). Large-scale resettlement efforts, as in Ethiopia or Indonesia, seemed to some analysts like attempts to remove or disorient potential dissidents. Attempts to 'villagize' scattered farmers or sedentarize mobile herders appeared as attempts more easily to tax, conscript, and regulate them (Scott, 1998). Economic anthropologists devoting new attention to farmer perspectives about contingency and safety found that consolidating scattered holdings into larger blocks, in the name of efficiency or mechanized monocropping, could stymie prudent efforts of family farmers to maintain parcels on varied lands to reduce their exposure to risks like plagues, floods, or droughts. 'Family and community dynamics and their agro-economic rationales came under closer scrutiny (McCay and Acheson, 1987; Netting, 1993). Links between material and symbolic concerns became more apparent (Goheen and Shipton, 1992; Shipton, 1994).' Postmodernist and poststructuralist scholars, meanwhile, eschewed the notion of timeless tenure 'systems,' preferring to see complexity, indeterminacy, negotiability, contestability, and historical contingency, in human interaction, and to draw attention to questions of differential power (Hann, 1998; von Benda-Beckmann et al., 2006). In town and country, they and others criticized tenure regimes based on race, class, and gender inequities (Lawrence and Low, 1990; LeBris et al., 1991).

Toward the turn of the millennium, a plurality of newly empowered indigenous voices in southern countries helped force scholars, administrators, and jurists concerned with land tenure everywhere to reassess their most basic terminology and philosophical premises (Agarwal, 1994). Assumptions of human dominion over land, of individualistic rights and duties, and of the sanctity of arbitrarily drawn borders and boundaries that blocked human movement all came under criticism.

Metaphor and Rhetoric

Human communication about land draws heavily on metaphoric imagery from the human body (headwaters, heartlands, fertility, etc.), kinship (motherland, fatherland), domicile (gateway to Asia), and other human-centered sources. Such metaphorizing imbues poetry and politics, while imagery of 'grounding' or 'terra firma' imbues legal and scientific discourse. English terms like 'property,' 'rights,' or 'ownership' sometimes carry culture-bound overtones of civilization, justice, or morality. To speak of land as a commodity denies psychological attachments to space and place. To speak of land as a 'resource' implies it exists to serve human use. Between people who assume that humans can own land and master it, and those who assume on the contrary that humans belong to the land and must respect it and conform to its requirements, communication easily goes awry.

People who derive their livelihood from land in different ways perceive and communicate about it in different geometric and geological idioms. Whether in the Andes, the Sahel, or Lapland, transhumant herders who must focus on linear access routes tend to clash with farmers who focus on fields along the way, when animals eat or trample crops. Seasonal and tidal wetlands and mudflats (as in the Niger delta, in the South Sudan's Sudd or along the Senegal River) are frequently contested by farmer-fishers, ecologists, and developers using different terminology.

Land and Tenure Reform

While land reform, in English, conventionally refers to redistribution of holdings, land *tenure* reform refers to changes in the more basic rules and understandings by which land is occupied, used, or transferred. Among many kinds of tenure reform are proclamation of sovereignty or eminent domain, implementation of titling (i.e., registration), and change in rules about transfer (loan, rental, sale, inheritance, etc.). Land reforms have a long history (Tuma, 1965). Dozens of

twentieth-century national tenure reforms sought to individualize or collectivize landholding.

Their histories are full of ironies and surprises. Frequently, reforms aimed at improving distribution of holdings have ended up worsening it, whether because of unequal information, implementer bias, deceit, or reneged deals. Moreover, reforms aimed at boosting production have often reduced it instead, for instance because new owners or occupants lacked farming experience or acquired the land only for speculation. Land tenure is so tightly bound up with kinship, religion, and other aspects of culture that a newly imposed tenure regime seldom expunges what was there before (Shipton, 1994). More often, it just crowds new procedures together with old, allowing the wealthy, powerful, astute, or well connected to gain at others' expense by manipulating confused or conflicting principles.

There are exceptional cases of successful land and tenure reform. One celebrated example is Taiwan's land redistribution in 1953, swiftly and efficiently implemented after a period of Japanese occupation had weakened local resistance. Attempts to emulate it elsewhere have seldom succeeded.

Bureaucratic Simplification

Bureaucratic administration, tending to push toward abstraction and universalism in its publicly professed goals, simplifies complex realities of human culture and ecology, sometimes beyond recognition, to make people or spaces susceptible to manipulation for taxation, military conscription, etc. Empty spaces on maps, or designations like 'vacant' or 'underproductive,' help justify land grabs, disfavoring swidden farmers, transhumant herders, foragers, and other occasional users. Titles issued to individuals ignore claims of dependents. But subjected people may thwart imposed tenure regimes, for instance by continuing to transfer fields without informing state authorities, as happened in Kenyan and other African cases of titling reforms over the second half of the twentieth century. Real and paper tenure diverge further.

Nowhere do real people live their lives consistently by capitalist or socialist principles, whatever they may think they do. In agropastoral Africa, for instance, land farmed by families or individuals may be expected to be opened for grazing by the animals of some broader public after harvest. Property shifts between public and private or remains subject to multiple tenure 'systems' simultaneously.

Collectivization and Villagization

Collective ownership and production have been part of utopian visions since Plato's *Republic* or before, and many different attempts have been made to bring these into reality in monasteries or other single- or mixed-sex religious or secular communes, sometimes modeled upon families. Mexico's *ejidos* after the 1910 revolution, and Israel's kibbutzim more recently, have been closely watched by admirers and critics alike. Marxist-inspired attempts to collectivize landholding under state aegis in the Soviet Union between 1917 and 1931, and in China after 1949, have been emulated in various parts of the world, notably eastern Europe, Vietnam and Cambodia (Kampuchea), Cuba, Tanzania, Ethiopia, and Lusophone African countries including Angola and Mozambique.

While late twentieth-century Chinese history has shown that some forms of state-organized collective farming can raise productivity, improve distribution of food and other vital resources, or both, if starting from a feudal or quasifeudal baseline, people in few parts of the world have been able to emulate socialist tenure reforms with lasting success. Commonly, work-incentive problems get in the way, and local populations chafe under centralized bureaucratic control of their lives.

Notable failures have been attempts to concentrate rural people into villages where the land could not sustain them, as in Tanzania's compulsory villagization from 1973 to 1976 (an experiment duplicated in Ethiopia a few years later). Similarly, savannah borehole well projects, for instance in Botswana or across the Sahel, have led to overconcentration of animals and overgrazing. Two policy conclusions on herders and farmers are clear enough: (1) people who live spread out, or mobile, usually have good reasons for wanting to stay that way; and (2) good intentions, in land tenure reforms, are about as likely to produce harmful as helpful results.

Titling and Individuation

Another kind of tenure reform is the titling or registration of individual claims for the first time. 'Private' property is often used to mean individual property, but the two need not be the same. State and local governments and landholding companies have several ways of registering land titles and transactions. Among the most commonly applied in former British colonies is the Torrens system, devised in Australia and New Zealand in the 1860s, where it allowed grid allotments for new settlers.

Where people already live, titling land in the names of individuals, under state guarantee, does not necessarily increase security of tenure as often assumed. It may decrease it. Instructive was the General Allotment Act (or Dawes Act) of 1887, by which the US government allowed for the awarding of individual land titles to Native Americans (or First Peoples). Between 1887 and 1932, about two-thirds of Native American lands were lost to immigrant settlers and speculators, who were not slow to exclude its former inhabitants and users.

British, French, and Belgian colonial administrations appear to have paid this story little heed in launching land titling programs in their colonies. Early twentieth-century titling initiatives were expanded to nationwide scale in the Kenyan model established under the Swynnerton Plan in 1954 and passed into law in 1957. That model, which still continues, was being emulated elsewhere in Africa at the turn of the millennium.

At least as often as not, land titling in new states and perhaps old seems to speed the concentration of holdings into fewer hands. Individuals newly freed of social constraints on selling, mortgaging, or pledging erstwhile family or clan land do not always make wise decisions. Speculators and accumulators use urban capital and rural off-farm incomes to buy out disadvantaged rural people in periods of drought, plague, or unfavorable prices.

The mortgage, a deadlined pledge linking land or other property to credit, plays a key part in this process (Shipton, 2009). Borrowers who fail to repay by a specified date forfeit their land to the lender or lender's agent. The mortgage appears regularly in histories of rural dispossession, not least in England, where law about it has changed many times, and in North America. While seemingly vital to urban and industrial economic life, in rural

areas mortgage loans are more treacherous to farming people, particularly where rainfall, infrastructure, and crop markets are unreliable. Although rich like poor may lose lands, mortgage foreclosure contributes heavily to class stratification. Inland tropical settings often lack sufficient industrial or commercial opportunity to absorb newly landless or land-poor people. Even where land titling is accepted, mortgaging is morally debated in many cultural and legal traditions. *Shari'a*, the sacred law of Islam, forbids mortgaging as sin.

When, and whom, is titling likely to help? Threatened indigenous minorities frequently seek titles to defend their home territories – and by extension, their livelihood and way of life – from more numerous and powerful outsiders who threaten to dispossess or displace them. These may include fortune seekers like ranchers and rubber tappers, as in Amazonia or Malaysia; homesteaders and land speculators, as in the American west; planters, as in the Caribbean; or politicians and their favorites, as in equatorial Africa.

Land titling is never a politically neutral process of recording information. Usually someone gains and someone loses. Gainers are often richer, better-connected, and better-schooled people; erstwhile land borrowers or land clients, who may become owners; and people who emigrate or seek to speculate in land without having to occupy or farm it. Losers include ancillary rightholders and dependents, and members of fast-reproducing families. Just as rural people have circumvented or resisted state directives to villagize or collectivize their landholding under socialist policies, as in Tanzania or Ethiopia, they have reasserted the rights of collectivities – clans, lineages, age sets, or voluntary associations – under individualistic capitalist ones, as in Kenya or Côte d'Ivoire in the late twentieth and early twenty-first centuries.

Land Rights and Tenure Security in Postsocialist Settings

Recent postsocialist decollectivization and privatization reforms have profoundly affected landholding patterns and rural institutions. Emerging from the need to dismantle the collective institutions imposed upon rural production in the socialist era, mass scale decollectivization efforts have had uneven and ambiguous results. While in some cases encouraging entrepreneurial initiative and small-scale farming, they have also led to legal and administrative ambiguities and a proliferation of alternative institutional arrangements with their own specific histories. The effects of the privatization reforms on the rise of viable smallholder production are particularly unclear and contextually diverse. In Russia, for example, privately held family farms have mostly failed to take off and former collective farms have continued operating as privatized joint-stock operations, characterized by complex and overlapping rental contracts and managerial reliance on the former elites (Miller and Heady, 2003; Lerman et al., 2004).

Experience from other former Soviet republics indicates similar continuities that build on pre-socialist traditions and cultural norms. In Estonia, popular aversion toward large-scale landholding had developed both in response to the earlier feudal estates of foreign overlords as well as more recent soviet collectivization reforms of the 1940s (Abrahams and Kahk, 1994). As all three Baltic republics – Estonia, Latvia, and Lithuania – had undergone forcible nationalization of agricultural lands during the socialist period, postsocialist mass restitution of land restored the family farms. Many of these still face severe structural constraints including unreliable markets, limited government subsidies, and poor access to agricultural credit (the last often a mixed blessing). In postsocialist contexts, land markets are often functioning poorly because of bureaucratic barriers and delays in legislative changes. In some cases, however, family farms have been relatively successful in surviving the massive tenure reforms. Radical socialist collectivization efforts in China like Mao's expansive 'people's communes' failed to eliminate households as farming units, and after Deng Xiaoping's decollectivization reforms of the 1970s household-based landholding made its return through lease contracts. Novel market opportunities in postsocialist China have helped raise smallholder production and local entrepreneurial initiative (Zhang and Donaldson, 2010) and fostered the somewhat paradoxical coexistence of kin-based moral economy and sharing with commercialized family farms (Brandstädter, 2003).

Both socialist and postsocialist land tenure reforms have significantly affected ecological systems and biodiversity. Socialist collectivization has brought along forcible sedentarization of pastoralists in many areas of Siberia, Mongolia, and elsewhere. The migration and mobility patterns of herder communities of the Soviet northeast have been profoundly altered by enclosures of pastures and establishment of stationary farming complexes, often turning the pastoralist subsistence economy into attempts at large-scale ranching for reindeer and other animals. The postsocialist decollectivization reforms have imposed their own organizational patterns for managing privatized herds, paradoxically reinforcing informal arrangements and alternative institutions for resource management (see Stammler and Ventsel, 2003 for a discussion of privatization reforms among Nentsy and Dolgan reindeer herders; Upton, 2012 for an analysis of endogenous and donor-initiated institutions of pastoralist management of Mongolia's Gobi region). The institutional changes brought along by the decollectivization reforms have also been associated with increasing abandonment of agricultural land. A comparative study of land abandonment in the first decade of postsocialist transition in several East European countries showed that the abandonment rates were lowest in the areas with least change in land use institutions from the socialist era, whereas countries with many new institutional regulations and delays in harmonizing legislative frameworks suffered from the highest rates of abandonment – for example, in Latvia, some 42% of all agricultural land in use in 1990 had been abandoned by 2000 (Prischepov et al., 2012: p. 1). The loss of crop and forest cover frequently affects first more marginal communities and ecosystems and can be associated with decreasing incomes from cultivation and a growing importance of nonfarm activities, as evidenced in Albania (Müller and Munroe, 2008).

In many postsocialist areas, the imposition of Western property models like private titling and land registration has failed to promote security of tenure or facilitate agricultural development. The rights-based models that seek land restitution to the former owners have failed to consider the multiple overarching entitlements and nodes of social control that characterize the lived experience of socialist and postsocialist agrarian communities (Humphrey, 1983). In the centrally planned economy, land property was governed by

administrative institutions and decrees rather than juridical ones, and it comprised an intricate mix of individual and collective obligations and entitlements that were not directly handled through the legal system (Hann, 2003; Verdery, 2003). Promoting exclusive land rights, postsocialist tenure reforms have not accounted for the intermediate layers of entitlement and social control between the landholder and the state that were present in socialist property systems, thereby overlooking actual property claims and mechanisms of their legitimation. Basic land use distinctions, like one between wet rice fields and upland rain-fed land in Vietnam, can involve different norms and modes of allocation, but such distinctions do not always survive tenure reforms (Sikor, 2006). Postsocialist landholding, mixing older and newer kinds of entitlements and collectivities, has been vulnerable to easy manipulation by different actors involved, complicating land restitution processes. Land property can thus not only become an important part of forging new social identities and political alliances, but at the same time inspire new kinds of competition and conflict.

The Contested Formalization of Land Claims

Particularly in postauthoritarian settings, land property claims are becoming central in continuing struggles over belonging, inclusion, and identity. Liberalization and decentralization reforms have brought new attention to issues of autochthony and tradition, highlighting the role of local forms of organization and authority in contestations over belonging and resource access (Geschiere, 2009). Competing public authorities strive to gain legitimacy by familiar idioms and vocabularies from local traditions and national bureaus, diversifying the rights and duties at different levels and scales as they variously attempt to formalize and regulate land matters locally and regionally (Lund, 2008). Hence, in Africa, south of the Sahara, a trend of 'informal formalization' of land rights, where new practices, institutions, and techniques for recording land rights and transactions arise locally, in parallel to the official ones of the state (Benjaminsen and Lund, 2003). These can involve novel-written contracts and testimonies and public oral witnessing for property claims well recognized yet outside the formal legal system, as shown by Lavigne Delville (2002) for francophone rural Africa. While creative, these processes have resulted in some fragmented land regimes, sometimes with seeming internal contradictions. Arguably, though, authority and property rights bolster each other in circular fashion: institutions or regimes that confer property rights sometimes seem, just by doing so, to gain an aura of legitimacy in the public eye (Sikor and Lund, 2009).

Displacement, Agrarian Encroachments, and Land Grabbing

Large numbers of people sometimes need to resettle as a result of development programs like irrigation schemes and hydroelectric dams, of military travel and war, and of environmental hardships like drought, or like chemical spills or radioactive contamination. Late twentieth-century anthropological studies of resettlement, notably by Elizabeth Colson, Thayer Scudder, and collaborators among Gwembe Tonga in Zambia (formerly Northern Rhodesia), showed how resettled people adjust to extreme stress and trauma in patterned and predictable phases. Among their problems is shaken confidence in whatever leaders are seen to have allowed the misfortune to happen. Helping or allowing communities or neighborhoods to move intact, insofar as their members wish, seems to mitigate the ill effects by keeping at least their social 'landscape' familiar. But no kind of human 'development' intervention is harder to orchestrate, or more prone to produce catastrophe, than forcing resettlement.

Many contemporary 'foraging' peoples reside in difficult environments not of their choosing, for instance in southern and central Africa and northern Canada, where 'race' discrimination has been a factor. Foraging, swidden farming, and mobile herding peoples worldwide suffered a varyingly steady diminution of their lands, and sometimes severe dislocation, from before the eighteenth until the late twentieth centuries, often in episodes where racism played a part (Ingold et al., 1988). The history of Native American foraging and farming peoples after Columbus – a story of military conquest, deceit, misrepresentation of consent, and treaty reneging by Euro-Americans – hit one of its low points in President Andrew Jackson's Indian Removal Act of 1830, which forced Cherokee, Seminole, and other settled agricultural Native Americans from their southeastern homes to Oklahoma, at the loss of thousands of lives. In another kind of extreme case, Australian law did not recognize the rights of indigenous (or Aboriginal) peoples to land until 1976. In the twentieth century, swidden farmers in tropical and subtropical zones worldwide faced serious threats to their livelihoods under encroachment from sedentary farmers, agribusinesses and other concerns, and under their own population growth. Loss of land for these peoples, as for foragers and pastoralists, has often meant disruption of culture and society in myriad, sometimes indirect ways.

Land grabbing for large-scale biofuel and export food cultivation has dramatically escalated in many parts of the world in recent years. Large monoculture plantations funded by foreign investment are threatening smallholder food security particularly in Africa, a continent often erroneously seen as a primary reservoir of underutilized land. The recent expansion in the production of biofuels, related to globally rising food and energy costs and growing demand for alternative energy sources, is adversely affecting African ecosystems and biodiversity, and weakening the livelihoods of poor and marginal groups (Matondi, Havnevik, and Beyene, 2011). Because of land tenure insecurity and complex and overlapping land rights, local communities are especially vulnerable to the lack of transparency in large-scale land acquisition contracts that often marginalize local populations. Local-level research is needed to evaluate the political, economic, and environmental impacts of the rapidly escalating land grabbing on poor smallholder communities worldwide.

Special Issues in Irrigated and Flood-Prone Lands

Irrigated lands sustain some of the world's highest rural population densities. But nowhere is control over land more hotly political than in irrigated areas, where central authorities commonly seek to dictate settlement, land and water allocation, inheritance, etc. Where flood control is a main concern, as

in much of irrigated China and Bangladesh, bureaucratic polities have tended to be highly centralized and authoritarian. Indeed, need for coordinating large numbers of people for flood control along rivers, and not just for irrigation, was among the main reasons why many such centralized, authoritarian state regimes arose as early as they did in Mesopotamia, Egypt, China, the Indus Valley, and elsewhere. Where river flooding poses less threat, as over much of agrarian Africa, regimes attempting to emulate highly centralized, authoritarian models have tended to enjoy less popular support, often proving fragile and short-lived – particularly where ethnic and linguistic mixing compounds the adjustment problems of living in close, compulsory synchrony.

Irrigation schemes frequently involve inequalities in access to water. The privilege of upstream location in the trench network, implying superior control over water, often coincides, as cause or effect, with personal or familial wealth and power of other kinds. The centripetal draw of high farm yields tempting farmers into irrigation schemes is sometimes counteracted by the centrifugal push of struggles over control over community and family life (as for instance in the Jahally Pachar rice scheme in The Gambia). Other problems common in irrigated areas include canal silting, and sluice gate aging and failure, difficulties of drainage and, where drainage fails, soil salinization – any of which can force resettlement.

Advocacy and Practice

The activist international defense of land rights of threatened indigenous minorities, particularly in sparsely settled regions pressed for new resource exploitation by outsiders (Amazonia, Alaska, central Africa, northern Australia, Irian Jaya, and elsewhere), crystallized in the Copenhagen-based International Work Group for Indigenous Affairs in 1968, London-based Survival International, in 1969, and Cambridge, Massachusetts-based Cultural Survival, Inc., in 1972, as well as other human rights defense groups. A worldwide movement of indigenous human rights groups, mutually emboldening, has raised public consciousness and achieved changes in national legislation like the Alaska Native Claims Settlement Act in 1971, Australia's Aboriginal Land Rights (Northern Territories) Act in 1976, and from Canada, the demarcation of Nunavut at the end of the century as a largely autonomous territory for First Peoples. Still, the International Labor Office's Convention 107, claiming that 'the right of ownership, collective or individual, of the members of the populations concerned over the lands which these populations traditionally occupy shall be recognized,' and the World Bank's tribal peoples policy, issued in 1982, have mainly been honored in the breach (Bodley, 1999). Participating in the active design of constructive tenure processes along lines more faithful to indigenous systems and aspirations, and showing respect to indigenous terminology, remains a challenge. Still, documents like the United Nations Declaration of the Rights of Indigenous People, passed in 2007, indicate that more principles of fairness, of respect, and (in this case) of resistance to colonization and dispossession have been making it into official policy at high levels and wide scales (United Nations, 2008).

New Frontiers

As social scientists and humanists look beyond simplistic dichotomies like public and private, collective and individual, or rights and duties, they perceive many yet unstudied forms of tenure. These may offer important solutions to work-incentive problems typical of socialism, on the one hand, and maldistribution problems typical of capitalism on the other. Other terms, concepts, and policy frameworks are needed that respect access, stewardship, and sentiments of attachment, that allow for possibilities of local autonomy and that permit human population flows between territories.

Shifting attention between micro- and macroscale, geographers, archaeologists, and others have sought to connect their work on the ground with findings newly accessible from 'remote sensing,' of landforms and land occupation and use, from air and space. Rural land tenure remains better studied than urban and periurban, and ground tenure better than water tenure. Border and boundary issues are land tenure issues on a large scale. Problems of land quality and distribution can be addressed not only by altering tenure regimes within nations, but also by allowing people to move between nations or continents more freely. Land tenure is not just about getting in or staying, but also about getting out.

Human territoriality and accommodation, if much studied, remain open for speculation on causes (Malmberg, 1980). A challenge for social and biological scientists alike is to connect the understandings about territoriality observable from human action on the land, with understandings becoming obtainable through ethology and the electrochemical study of the human brain. Human biology has yet produced few if any conclusive findings about territorial instincts in humans, but enough species exhibit recognizable social and cultural patterning in their territorial relations to make it seem unlikely that human spatial perceptions and attachments result from uniquely human social or cultural processes alone.

Meanwhile, as more languages have become involved in the academic study of land and tenure, the reexamination of the most familiar, but deeply cultural and potentially exotic, concepts and categories – like 'land,' 'property,' and 'rights' – has continued.

Land-Use Indicators

Karl-Heinz Erb, Institute of Social Ecology Vienna, Alpen-Adria Universität Klagenfurt, Vienna, Graz, Austria

Abstract

Land use denotes the sum of human activities and arrangements aimed at harnessing terrestrial ecosystem services. Land use is a central element of society–nature interactions and a pervasive driver of global environmental change. Metrics for land use refer to two aspects: area extent of certain land-use types and the intensity of land use within a certain land-use type. Land-use intensity encompasses metrics for inputs to the land-based production system, for output for the production systems, and system-level changes induced by land use that impact upon ecological and social systems (e.g., impacts on ecosystem parameters). This article presents different prominent biophysical indicators for land use, and discusses their reference systems (production vs consumption, spatially explicit vs administrative units) as well as their position in the drivers-pressures-state-impact-response (DPSIR) indicator system framework.

Land use denotes the sum of human activities and arrangements aimed at harnessing services provided by terrestrial ecosystems. Land use is a central element of society–nature interactions and a pervasive driver of global environmental change (Turner et al., 2007). One of the central functions of land use is the provision of resources to society, an essential and not substitutable resource for many purposes. This includes, in particular, the provision of food, feed, fuel, fibers, and also clean water and air (Millennium Ecosystem Assessment, 2005). Besides these provisioning functions, land provides many other services to society: it hosts infrastructure, absorbs wastes and emissions, and represents a source of recreational, esthetical, spiritual, and cultural values (Millennium Ecosystem Assessment, 2005). But land not only provides services to human society, it also represents the basis of terrestrial biodiversity (e.g., by providing habitats and gene reserves for plants, animals, and micro-organisms, above and below ground). Furthermore, terrestrial ecosystems are major components of the global climate systems and strongly connect to biogeochemical cycles of, e.g., carbon, nitrogen, phosphorous, and water. By using the land, human societies alter ecological pattern and processes in order to maximize the output of certain services, often at the expense of others (Foley et al., 2005). Land use directly and indirectly relates to many of the grand sustainability challenges (Reid et al., 2010) and is at the center of the three 'Rio conventions' by the United Nations (the United Nations Convention on Biological Diversity, CBD, the United Nations Convention to Combat Desertification, UNCCD, and the United Nations Framework Convention on Climate Change, UNFCCC). Land use is also a central research theme of Social Ecology (*see* Social Ecology).

Land is a finite resource (the terrestrial ice-free surface amounts to approximately 130 Mio km^2), and more than three quarters of it are currently used by humans (Sanderson et al., 2002), with more or less strong effects on ecosystem properties, depending on the type and intensity of use. One of the most ostensible effects of land use are land-cover changes. Land cover denotes the observed biological and physical attributes of Earth's terrestrial surface, such as vegetation or human-made artifacts (*see* Land Change: The Merger of Land Cover and Land use Dynamics).

Metrics of Land Use

Indicators are symbolic representations designed to communicate a property or trend in a system that is inaccessible to direct description due to its internal complexity (Hák et al., 2007). Indicators provide information on the state of a phenomenon of interest and fulfill, in general, three purposes: (1) simplification, (2) quantification, and (3) communication. Indicators have to fulfill the criteria of soundness, relevance, and practicability (e.g., data availability). This article discusses biophysical sustainability indicators for land use (*see* Sustainability and Sustainability Science).

In general biophysical land-use indicators refer to two aspects of land use. (1) The extent of land use, usually measured in m^2, ha, or km^2, and its change in time such as the expansion or contraction of a certain land use at the expense of another. (2) The intensity of land use. Land-use intensity encompasses the levels of socioeconomic inputs (e.g., labor, resources, water, energy, or capital) and/or altered output (value or quantity) per unit area (Erb et al., 2013; Kuemmerle et al., 2013). There is no unequivocal unit for measuring land-use intensity, but it strongly depends on the perspective and system of reference (see below). It is important to note that changes in intensity need not necessarily result in changes in land cover but occur within the same land-cover type.

Area-Related Indicators

The most intuitive metrics for land use refer to the extent of a certain land use. A prominent example is the extent of cropland and its expansion into pristine forests, a currently still widespread trend in particular in the tropics; it gained attention due to its far-reaching effects on global biodiversity and perturbations of the global carbon cycle. Other examples are the extent of forest, of organically farmed cropland, of areas with natural protection status, of fragmented areas, or of areas subject to or restored from degradation, within a given territory, and the respective changes over time. These metrics allow to draw conclusions on state and trends of the environment.

Methodologically, the development of area-related land-use indicators relies on the use of nominal scales and the unambiguous assignment of a discrete unit (class) to land-use types. The use of nominal information is powerful as it allows to quantified, map and traced land use through space and time. This, however, is complicated by the fact that land-use activities usually consist of different sub-activities (e.g., cropland agriculture consists of sowing, plowing, harrowing, weeding) which are often cultivar and purpose specific and thus performed with different intensity. Different land-use activities are often highly integrated, encompassing different types of land use, such as with agroforestry. Unambiguous attribution of land-use types is thus often intricate. Moreover, nominal scales are limited in analyzing continuous, functional processes, such as quality aspects of land use or land-use intensity (Erb, 2012).

Area-related land-use indicators are closely linked to the concept of land cover (*see* Land Change: The Merger of Land Cover and Land use Dynamics) and, in general, discern major land-use types such as cropland (arable land and permanent crops), infrastructure areas (urban and transport), forests used for forestry, grasslands, areas devoid of land use (wilderness), and protected areas (e.g., natural parks, nature reserves). As large areas cannot be unambiguously attributed to all of these classes, a certain fraction of land area is often labeled 'other land' without further specification. Land-use classifications are especially powerful in cases where land use closely relates to a specific with land cover, such as is the case with infrastructure use or cropping. In such cases, one can capitalize on the remarkable progress made by remote sensing techniques, which allow generating cheap, consistent, spatially explicit land-cover datasets with wall-to-wall representation, usually compiled in Geographic Information System (*see* Geographic Information Systems and Remote Sensing).

In cases where land use is not bound tightly to a certain land-cover type or ecosystem, the development and application of area-related indicators for land use is much less straightforward and prone to misconceptions. Prominent examples are the definitions of forests (land cover) and forestry (land use). First, definitions of forests differ significantly among different data sources, referring to different combinations of characteristics such as fraction of crown closure or tree height. This results in difficulties to track the extent of forests (Grainger, 2008). Second, forests can be used for other purposes than timber harvest, e.g., grazing, and individual plots of used forests might be tree-less, as is, e.g., the case with clear-cut areas in dense forests which are allowed to regrow. Such examples that lead to complex problems of attribution are not the exception, but the rule, and apply to almost all broad types of land use: Fallow areas as intrinsic features of less-extensive arable land farming or livestock that grazes in many ecosystems, including forests, semi-deserts, natural and artificial grasslands are but examples to illustrate this (Erb, 2012).

Structural Landscape Elements

In landscape ecology, indicators for landscape structures, i.e., the form of structural elements, have been developed and successfully applied to socioecological analyses (Forman and Godron, 1986). Several indicators for landscape heterogeneity have been developed in this discipline. Heterogeneity relates to differences and diversity within a landscape and discerns elements such as patches, matrix, and corridors. Patches are identified as the spatial units of a landscape, which are embedded in the matrix and may be connected by corridors. From the spatiotemporal characteristics of patches and corridors, indicators for, e.g., the connectivity of the landscape are developed: A high spatial connectivity, usually beneficial for species richness in an area, is given either when the patches are sufficiently close that movement can occur among them, or that there is some corridor along which the organisms can move. In general, human influence is found to result in a simplification and geometrization of landscape pattern, with detrimental effects on the provision of ecosystem services and biodiversity (Millennium Ecosystem Assessment, 2005). In consequence, metrics of the size, shape, number, and configuration of patches and corridors are used as surrogate indicators for biodiversity endangerment and/or land-use intensity.

Land-Use Intensity Indicators

A focus on the extent of land use neglects important aspects that relate to many, benign as well as detrimental, consequences of land use. The quantification of the intensity of land use deserves particular attention with this regard, as it is recognized as one of the most pervasive factors of global environmental change (Foley et al., 2005; Ellis et al., 2013). For instance, empirical analyses revealed that effects of land-use intensity (changes) on many Earth system components, such as energy flows or micro climate, can be of similar magnitude as land-cover changes (Luyssaert et al., 2014).

In recent decades, due to the widespread availability of spatially explicit land-cover datasets, the major focus of research on land use lies with land cover (changes), while other land-use changes (sometimes denoted 'subtle,' i.e., occurring within land-cover types) gained less attention (Erb et al., 2013; Kuemmerle et al., 2013). This is surprising, because studies on the intensity of land use reach back to the founders of economics such as Malthus, Riccardo and Von Thünen and re-gained impetus in the 1960s and 1970s with the seminal paper by E. Boserup on the *Conditions of Agricultural Growth* (Boserup, 1965). Studies of land cover are usually dominated by natural science approaches, while social sciences typically focus on land use, integrating these two perspectives is high on the agenda of land system science (GLP, 2005).

Land-use intensity is characterized by three core elements of measure (Erb et al., 2013; Kuemmerle et al., 2013): (1) inputs to the production system, (2) outputs from the production system, and (3) changes in ecosystem properties. All these elements are differently pronounced in different disciplines. While (1) and (2) directly relate to concepts such as the socioeconomic metabolism (Erb, 2012) and are established research themes in land-related research, e.g., not only in economics in the form of the production functions (in monetary units), but also in geography or anthropology, and (3) refers to (changes) in system states of ecosystems, a research strand that gained impetus in particular in natural-science-oriented research strands (Erb et al., 2013).

Output Intensity

Output indicators encompass the outputs of land to society, most prominently the amount of produce per time period and

unit area (e.g., tons of cereals harvested, milk produced, or timber removed from forests per hectare and year). While measuring output appears straightforward, the development of robust and comparable indicators is intricate. These intricacies related to (1) the unit of measurement and (2) the methodology used to measure output consistently (Erb et al., 2013). Results of output intensity measurements can vary considerably when different units are used, e.g., mass fresh weight, mass dry matter, volume, energy, calorific value, or monetary value per area and year, and with regard to the reference system: agricultural areas or industrial sectors. Indicators for meat production, e.g., can be expressed as live animals per unit area (stocking density), meat output per fodder input (feed conversion ratio), or the carcass weight of animals, all of which yield different insights in the intensity of the land-based production process. Moreover, comparability of results is also hampered due to the fact that the yields in agriculture and forestry can vary widely due to differences in climate, soil conditions, or management, and are specific for individual cultivars or cultivar groups. This renders the simple use of yield data as surrogates for output intensity problematic.

Methods have been developed that take these differences in production conditions into account. Among those, the 'yield gap' method has gained attention. 'Yield gaps' denote the difference between agricultural yields at the plot, farm, or regional level to a reference yield that is attained under similar conditions of production, i.e., in the same region, but with optimal management (e.g., Lobell et al., 2009). Furthermore, on cropland the measurement of output appears to be intuitive and simple, but it is often complex: Because in most production systems a considerable fraction of the total cropland is periodically left fallow to maintain the soil fertility, it is important to relate the outputs to the full production cycle to generate comparable values. Such data, however, are usually not readily available or are highly uncertain (Kuemmerle et al., 2013).

Input Intensity

Metrics of input intensity quantify inputs to the production system. Here, the substitution of capital, labor, and skills against land is at the center of attention, which stimulated the development of land-use intensity indices based on (combinations of) input data, such as fertilizer application or labor input per unit cropland and year, mechanization, etc. One pivotal input indicator for input intensity is cropping intensity, i.e., the land actually under production (counted each time it is harvested in multicropping) divided by the total cropland extent (Boserup, 1965). For cropland with fallows cycles, this indicator is between 0 and 1, for multicropping, >1. The focus on this indicator is based on the observation that, under preindustrial conditions, the annual crop yield of a parcel of land can scarcely be enhanced, and only an increased cropping frequency can increase production. Similarly, rotation length is an important intensity indicator in forestry. The cropping intensity index gained particular attention in anthropology and was expanded by, e.g., indicators that consider the different lengths in fallow and cropping period or indices for used technologies (Shriar, 2000).

Intensity Indicators at the Ecosystem Level

The systematic observation of the effects of land-use intensity on the ecological patterns and processes, such as nutrient cycling, biodiversity, net primary production (NPP; *see* Energy Flow Analysis), carbon storage, water quality, and water retention capacity, is an important component for a comprehensive analytical framework for land-use research (GLP, 2005). Metrics that relate to alterations of system properties can also be used to develop indicators for land-use intensity.

Quantifying the effects of changes in the ecosystem parameters and consequential alterations of the provision of ecosystem services, thus, appears central for developing indicators of system-level outcomes. While the measurements of effects of such alterations on the provision of ecosystem services have proven to be difficult (Haines-Young et al., 2012), indicator systems that aim at quantifying these changes at the system level have been suggested. These approaches assess the differences between the actual and potential states of the ecosystem, and use this 'distance' as a surrogate indicator for land-use intensity (**Figure 1**). This notion is closely related to the ecological definition of disturbance (Pickett and White, 1986). Examples for such approaches include the spatial inventories of the density of human artifacts on the Earth's surface (Sanderson et al., 2002), or the land use and disturbance intensity index proposed for forestry, as based on the ecological law of self-thinning (Luyssaert et al., 2011).

In line with this notion, the concept of 'hemeroby' describes gradients of human influence on landscape and flora and is

Figure 1 Indicators for land-use intensity integrate socioeconomic investments and inputs to land, outputs, and benefits gained from land and the system-level changes induced by management, which can be quantified as 'distance' between potential and actual state.

also conceptualized along the lines of disturbance and gained attention in land-use planning (Naveh and Lieberman, 1990) and the integration of land-use-related aspect such as biodiversity loss in Life Cycle Analyses (LCA). The hemeroby concept closely relates to the concept of naturalness and classifies landscape elements on an ordinal scale from levels of no human influence ('ahmemerob') to purely artificial and the related ecosystems and vegetation ('metahemerob') in varying graduations. Input data include the share of life-forms (e.g., trees, shrubs, grasses) and introduced species of vascular plants in the prevailing plant association, as well as by parameters that describe human impacts on ecosystems such as land-use types, plant communities, and soils.

Another surrogate indicator is the indicator 'ecological integrity' (Pimentel et al., 2000). Ecological integrity refers to the stability of biotic communities and relates to the idea of naturalness (see above) and 'ecosystem health,' in analogy to human health. Land use is conceptualized as reducing the degrees of freedom for natural processes to self-organize, i.e., their integrity; thus, major emphasis is put on the supporting ecosystem function such as NPP, soil formation, or nutrient cycling.

One prominent indicator that relies on a comparison of potential and actual state of a fundamental ecosystem process, i.e., NPP, is the land-use intensity indicator 'human appropriation of net primary production' (HANPP). This indicator, proposed in the late 1980s by Vitousek et al. (1986) and was further developed since (Haberl et al., 2007a; Krausmann et al., in press) and closely relates to and expands the concept social metabolism. HANPP assesses changes in the availability of NPP (*see* Energy Flow Analysis) for ecological processes induced by (1) alterations of the productivity of vegetation that result from land use and (2) extraction of NPP from ecosystems through biomass harvest. One example is forest clearing for agricultural purposes: the replacement of forests with arable land considerably affects (and predominantly decreases) NPP. Second, harvest removes NPP from the ecosystem in the form of biomass, thereby reducing the amount of available biomass remaining in the ecosystem for all heterotrophic food chains or for biomass accumulation. These two processes can either be expressed in the unit of biomass, carbon, or energy flow per year and area assessed by calculating the difference between the NPP that would prevail (hypothetically) in the absence of land use and the NPP that actually remains in ecosystems, i.e., after harvest. Because NPP is a central resource for society as well as for natural processes, HANPP is a valuable socio-ecological concept that systematically integrates socioeconomic (biomass harvest) and ecological information (NPP) and thus is accessible for socioeconomic as well as ecological research (Erb et al., 2009). A particular important aspect of HANPP is the close interrelation between energy flows in ecosystems and biodiversity, asserted in the so-called 'species-energy hypothesis: HANPP, i.e., a metric of the alteration of energy flows in ecosystems, has been found to be a robust land-use indicator for biodiversity endangerment (Haberl et al., 2007b).

Many more system-level indicators have been developed and could be used as system-level indicators for land-use intensity indicators, e.g., the effect of land use on terrestrial carbon stocks, on nitrogen, or water cycles. Datasets, however, that would allow for straightforward assessments are still rare, particularly at the supranational level (Kuemmerle et al., 2013).

Integrated Indicators

A few land-use indicators have been proposed that integrate two or more dimensions of land use. Agricultural yield, for instance, is already a combination of output and input metric: produce per land area subject to production. The indicator 'energy return on investment' (EROI; *see* Energy Flow Analysis), important in system-level and product-level approaches alike, balances energetic inputs and outputs to and from land and can illustrate the net-effects of intensification strategies and allows for insights in the interrelation of land-use intensity and efficiency. Moving beyond analyses of input–output relations, one can go for analyzing the interrelation between intended and unintended effects of land use. However, only a few examples exist: HANPP, e.g., allows to systematically linking land-use outputs (harvest) with the energetic change caused in the ecosystem, i.e., to calculate the HANPP-efficiency of land use. Similar developments are required as they would provide the basis for systematic analysis of the trade-offs and synergies related to land use such as land competition (Smith et al., 2010) and effects on climate change mitigation (*see* Land Change: The Merger of Land Cover and Land use Dynamics), or food security.

Spatial Reference of Land Use Information

Both, social and natural processes are highly diverse in space, which renders the generation of land-use indicators intricate. Most datasets related to natural processes, and thus also land cover, are available in spatial grids. Besides thematic problems of homogenous, comparable legends, maps also differ with regard to geographic protection and spatial resolution, and need to be reconciled in GIS environments (*see* Geographic Information Systems and Remote Sensing). However, pixels, or grid cells, are not system entities of socioeconomic processes. Land-use datasets, in contrast, are usually available for administrative units, which are the decisive spatial units for the organization and management of natural resource use. The development of spatial data which bridge the different spatial scales of ecological, social, and socioeconomic processes is required for the development of land-use indicator systems (Liverman et al., 1998).

Production and Consumption Indicators

Many land-use indicators refer to the ecosystem or the place of land use, and thus follow a production perspective. Alternative indicators that follow a consumer's perspective have been proposed that systematically link production and consumption. The principle of these accounting schemes, related to the concept of LCA, is displayed in **Figure 2**. These frameworks allow to study drivers of land use and land-cover change (demand for commodities is among the most important land-use drivers) as well as phenomena such as displacement of land

Figure 2 Production–consumption interlinkages. Arrow sizes are proportional to global flows of biomass from Haberl, H., Erb, K.H., Krausmann, F., Gaube, V., Bondeau, A., Plutzar, C., Gingrich, S., Lucht, W., Fischer-Kowalski, M., 2007a. Quantifying and mapping the human appropriation of net primary production in earth's terrestrial ecosystems. Proceedings of the National Academy of Sciences USA 104, 12942–12947.

use or leakage (Meyfroidt et al., 2013; *see* Land Change) induced by the international trade of commodities.

A simple consumer-based land-use indicator is the Ecological Footprint. Instead of calculating the extent of land use within a territory, it assesses the area demand required by society to sustain its apparent consumption of resources and goods, i.e., domestic production plus imports minus exports (*see* Material Flow Analysis; Energy Flow Analysis). Ecological footprint studies evaluate how much land is needed to produce the biomass consumed, to host infrastructure, and to absorb wastes, above all, CO_2 generated by a human population, and compare this footprint to the global or national average per-capita area availability of land. In its original version, an Ecological Footprint analysis uses the unit 'global hectares' by calculating the area that would be necessary to maintain these flows on the global average, i.e., using global average yields per cultivars in any given year and weighing different land-use types according to their contribution of global biomass flows.

Whereas on a global level the interpretation of a footprint calculation is straightforward, as neither trade nor differences in agricultural yields distort the picture, the interpretation of ecological footprint results is intricate at sub-global levels. Furthermore, ecological footprint assessments do not provide information on the actual size of land under use, but rather on the share of global biological production a society requires (expressed in the unit 'global hectares'). In consequence, the footprint approach has been modified in order to be able to monitor land requirements whilst avoiding this central shortcoming of ecological footprint analyses. Such approaches assess the extent of land use domestically and abroad in a manner compatible with other forms of monitoring land use, e.g., remote sensing and resource use, such as MFA and EFA (Erb, 2004; *see* Material Flow Analysis; Energy Flow Analysis).

These intricacies as well as the problem of multiple land use led to the development of the embodied HANPP (eHANPP) concept (Haberl et al., 2012). The eHANPP concept systematically links the amount of HANPP caused by land use to the consumption of final land-based products. By focusing on NPP, this concept allows to overcome one of the central weaknesses of land demand studies: the extent of land use is usually not a good indicator for the associated ecological impact. For instance, areas can be used intensively or extensively, and environmental damage is strongly associated with the intensity of certain land-use practices. Furthermore, land can be used several times a year (e.g., intercropping, agroforestry), while annual NPP can only be used in once if no stocks are to be depleted. In contrast to resource use indicators, such as those derived with MFA techniques (*see* Material Flow Analysis), fossil–energy related CO_2 emissions or the ecological footprint, eHANPP is only loosely correlated to GDP, which can be explained by improvements in agricultural efficiency associated with GDP growth (Haberl et al., 2012). eHANPP studies thus allow to cover land use aspects that are not grasped by other resource-use indicator systems.

Indicator Systems

A widely applied Indicators classification system for environmental and sustainability concerns is the pressure-state-response (PSR) scheme put forward by the OECD, or its extended version, the DPSIR scheme (driving forces-pressures-states-impacts-response) framework by the European Environmental Agency. This framework allows to categorize indicators by distinguishing different levels or reference systems of indicators: (1) driving forces and (2) pressures on the environment (in land use studies these two are often denoted as ultimate and proximate causes), (3) state indicators (including system-level indicators for natural processes or variables describing the natural environment), (4) impacts (effects on ecological or social systems, mostly unintended), and (5) responses (activities following undesired impacts that can be targeted at any part of the chain between driving forces and impacts). A sound indicator system consists of the balanced set of these five types of indicators, as none indicator can grasp the multitude of dimensions related to sustainability (Hák et al., 2007).

The DPSIR scheme gained particular attention in land-use planning and decision making as it well addresses the policy life cycle (Hák et al., 2007), schematically illustrated in **Figure 3**.

Figure 3 The DPSIR scheme, associate information flows and policy actions. Source: Compiled from Hák, T., Moldan, B., Dahl, L., 2007. Sustainability Indicators: A Scientific Assessment, Scope. Island Press.

The DPSIR scheme allows identifying a broad spectrum of indicators. The above-discussed biophysical indicators can be embedded in the DSPIR scheme and complemented by economic and social indicators. Biophysical indicators that depict the production–consumption disparity operationalize driving force indicators, next to indicators for socioeconomic development such as GDP, profit contribution of farms, or income distribution. Indicators that refer to land-use extent and input–output intensity represent pressure indicators. System-level intensity as well as spatial heterogeneity are state indicators that closely link to impacts such as biodiversity loss, degradation, or the loss of other ecosystem services. Here also social indicators such as health impacts and their social distribution. Responses include activities focusing on impacts (e.g., restoration programs), states (conservation programs), pressures (standards for agricultural inputs, harvest allowances), and driving forces (e.g., technological development programs).

Conclusion and Outlook

Land use provides the biophysical basis of human societies and is at the same time a pervasive factor of global environmental change. Land represents a confined resource, of which almost three quarters are currently used for infrastructure, cropping, grazing, or forestry, and at varying degrees of intensity. The demand for land is anticipated to increase, however, due to a growing and increasingly affluent world population that aims at satisfying consumption needs. Improving our still limited understanding of land use (change), its driving forces and constraints as well as its impacts on ecological as well as on social systems, is a central mandate of sustainability science.

Land-use-indicator systems that allow to measure and monitor the many aspects of society–nature interlinkages related to terrestrial ecosystems play a central role in this context. The development of such systems can build on a rich tradition and approaches established in disciplines such as ecology, geography, anthropology, and economics. Furthering these approaches by bridging disciplinary boundaries and making use of the plurality of scientific perspectives is particularly fruitful, but also required to close knowledge gaps, reduce uncertainty, and enhance our forecasting and monitoring capabilities. The nature of the present sustainability challenges, such as climate change, biodiversity conservation or food security, requires interdisciplinary, integrated approaches in order to produce effective, useful information for policymakers and practitioners, as well as for stakeholders.

Language Acquisition

Brian MacWhinney, Carnegie Mellon University, Pittsburgh, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Adults often underestimate the size and scope of the social, cognitive, and motoric challenges that children face when learning language. In fact, language learning is the most complex task that any of us will master, and the fact that we all succeed in learning our native language reflects the extent to which language is shaped to conform to the abilities we all possess.

The ability to learn language is present in almost every human child. Children who are born blind have no problem learning to speak, although they may occasionally be confused about words for colors or locations. Children who are born deaf readily acquire a rich system of signs, as long as they are exposed to native sign language speakers. Even a child, like Helen Keller, who has lost both hearing and sight, can still acquire language through symbols expressed in touch and motion. Children with neurological disorders, such as brain lesions or hydrocephalus, often acquire complete control over spoken language, despite some early delay (MacWhinney et al., 2000). Children with the most extreme forms of mental retardation are still able to acquire the basic units of human communication. Given this pervasiveness and inevitability of first-language acquisition, we often tend to take the process of language learning for granted. But language is the most complex skill that a human being can master. The fact that nearly all of us succeed in this task indicates how remarkably well the structure of language adapts to our underlying abilities. Language is immensely complex, but its complexity is accessible to all of us because it is uniquely crafted to fit our human nature (Christiansen and Chater, 2008).

We can look at language acquisition from different perspectives. Of these, the three most fully developed are those of the linguist, the psychologist, and the educator. Linguists tend to think of language as having a universal core from which individual languages select out a particular configuration of features, parameters, and settings (Chomsky, 1982). From this perspective, child language is an interesting slice of the universal pie. The shape of this slice is presumably limited by both formal universal constraints and the child's mental abilities or developmental status.

Psychologists (MacWhinney, 1998) look at language learning from a very different perspective. To the psychologist, language acquisition is a window on the operation of the human mind. This window allows us to view the structure and functioning of neural circuits in the brain. It also allows us to understand how these circuits support processes such as reinforcement, generalization, imagination, and thinking. To understand these processes better, psychologists conduct controlled experiments in which children learn new words, sounds, and rules. They may measure these processes using neural imaging techniques, or they may simply study the changes in the language of the child across time.

Educators and parents are typically interested in understanding how to use language learning to promote children's overall social, emotional, and cognitive development. Working within the tradition of sociocultural theory, as articulated by Vygotsky (1934), these researchers examine the ways in which children use words in specific games and interactions with their parents as a way of acquiring the patterns of their culture (Nelson, 1998).

Important and engaging though these adult perspectives may be, the best way to appreciate the dynamics of language development is to assume the perspective of the child. In particular, we need to understand the specific challenges that language learning presents to the child and the ways in which each is overcome. For detailed data on actual interactions between children and their parents, readers are encouraged to browse the many recordings and transcripts to be found at http://childes.talkbank.org.

Early Audition

William James (1890) described the world of the newborn as a "blooming, buzzing confusion." However, on the auditory level, the newborn's world is remarkably well structured. The cochlea and auditory nerve provide extensive preprocessing of signals for pitch and intensity. In the 1970s, researchers discovered that human infants were specifically adapted at birth to perceive contrasts such as that between 'p' and 'b,' as in *pit* and *bit*. However, subsequent research showed that even chinchillas are capable of making this distinction (Werker, 1995). Thus, it appears that much of the basic structure of the auditory world can be attributed to fundamental processes in the mammalian ear.

Beyond this basic level of auditory processing, it appears that infants have a remarkable capacity to record and store sequences of auditory events. For example, if a 6-month-old hears a string of nonsense syllables such as *badigudibagadigudigagidu* repeated many times, the parts that are repeated will stand out and affect later listening. In this example, the repeated string is *digudi*. If infants are trained on such strings, the repeated segment will first pop out, and then they will grow tired of this sound and will come to prefer to listen to new sound strings rather than those that have the boring old *digudi* string (Thiessen, 2009). These habituation effects are strongest for stressed syllables and syllables immediately following stressed syllables.

Recent studies of these effects in auditory memory suggest that we are born with an ability to store and recall the sounds of human language. It is as if the infant has a tape recorder in the auditory cortex that records input sounds, replays them, and accustoms the ear to their patterns.

Babies also demonstrate preferences for the language that resembles the speech of their mothers. Thus, a French infant will prefer to listen to French, whereas a Polish infant will prefer to listen to Polish (Jusczyk, 1997). In addition, babies demonstrate a preference for their own mother's voice, as opposed to that of other women. Together, these abilities and preferences suggest that during the first 8 months, the child is remarkably attentive to language. Although children are not yet learning words, they are acquiring the basic auditory and intonational patterns of their native language. As they sharpen their ability to hear the contrasts of their native language, they begin to lose the ability to hear contrasts not represented in the native language. If the child is growing up in a bilingual world, full perceptual flexibility is maintained. However, if the child is growing up in a monolingual world, flexibility in processing is gradually traded off for quickness and automaticity.

Early Articulation

During the first 3 months, a baby's vocalizations are nothing more than cries and vegetative adaptations. However, around 3 months, at the time of the first social smile, babies begin to make the delightful little sounds that we call 'cooing.' These sounds have no particular linguistic structure, but their well-integrated intonation makes them sure parent pleasers. By 6 months, the baby is producing structured vocalizations, including a larger diversity of nasals, vowel types, and syllables with the canonical consonant–vowel (CV) structure. The basic framework of early babbling seems to be constructed on top of patterns of noisy lip smacking that are present in many primates (MacNeilage, 1998). These vocal gestures include some form of vocal closure followed by a release with vocalic resonance. Essentially, this is the CV syllable in which a consonant is followed by a vowel.

Until the sixth month, deaf infants continue to babble normally. However, by the age of 9 months, deaf infants lose their interest in babbling. This suggests that earlier babbling is sustained largely through proprioceptive and somaesthetic feedback, as babies explore the various ways in which they can play with their mouth. After 6 months, babbling relies increasingly on auditory feedback. During this period, the infant tries to produce specific sounds to match up with specific auditory impressions. It is at this point that deaf children no longer find babbling entertaining, since they cannot obtain auditory feedback. These facts suggest that, from the infant's point of view, babbling is essentially a process of self-entertainment.

In the heyday of behaviorism, researchers analyzed the development of babbling in terms of reinforcement theory (Mowrer, 1960). They thought that process of producing reinforcing sounds like the sounds made by the child's mother would lead a Chinese baby to babble the sounds of Chinese, whereas a Quechua baby would babble the sounds of Quechua. This was the theory of 'babbling drift.' However, closer observation of the babbling of 8-month-olds indicates that virtually no such drift occurs. By 12 months, there is some slight drift in the direction of the native language, as the infant begins to acquire the first words. Proponents of universal phonology have sometimes suggested that all children engage in babbling all the sounds of all the world's languages. Here, again, the claim seems to be overstated. Although it is certainly true that some English-learning infants will produce Bantu clicks and Quechua implosives, not all children produce all of these sounds.

The First Words

The child's ability to produce the first word is based on three earlier developments. The first is the infant's growing ability to record the sounds of words. The second is the development of an ability to control vocal productions that occurs in the late stages of babbling. The third is the general growth of the symbolic function, as represented in play, imitation, and object manipulation. Piaget (1954) characterized the infant's cognitive development in terms of the growth of representation or the 'object concept.' In the first 6 months of life, the child is unable to think about objects that are not physically present. However, as infants learn more about objects, they become able to associate their properties with their own actions and other features of the context. In this way, subtle cues can be used to dredge up fuller representations from memory. For example, a child may see a dog's tail sticking out from behind a chair and realize that the rest of the dog is hiding behind the chair. This understanding of how parts relate to wholes supports the child's first major use of the symbolic function. When playing with toys, the 12-month-old will begin to produce sounds such as room or bambam that represent properties of these toys and actions. Often these phonologically consistent forms (Peters, 1983) appear before the first real words. Because they have no clear conventional status, parents may tend to ignore these first symbolic attempts as nothing more than spurious productions or babbling.

Even before children have produced their first conventional word, they have already acquired an ability to comprehend as many as 10 conventional forms. They learn these forms through frequent associations between actions, objects, and words. Parents often realize that the prelinguistic infant is beginning to understand what they say. However, they are hard pressed to demonstrate this ability convincingly. Researchers deal with this problem by bringing infants into the laboratory, placing them in comfortable high chairs, and asking them to look at pictures, using the technique of visually reinforced preferential looking (Schafer and Plunkett, 1998). A name such as dog is produced across loudspeakers. Pictures of two objects are then displayed. In this case, a dog may be on the screen to the right of the baby and a car may be on the screen to the left. If the child looks at the picture that matches the word, a toy bunny pops up and does an amusing drum roll. This convinces babies that they have chosen correctly and they then do the best they can to look at the correct picture on each trial. Some children get fussy after only a few trials, but others last for 10 trials or more at one sitting and provide reliable evidence that

they have begun to understand a few basic words. Many children show this level of understanding by the tenth month – often 2–3 months before the child has produced a recognizable first word.

Producing the first word is a bit like stepping out on stage. When babbling for their own entertainment, the only constraints that infants face are those arising from their own playfulness and interest. If they want to play around with a particular articulatory pattern or sound, there are no problematic consequences. However, when faced with the task of producing word forms, the child's articulation has to be extremely accurate and within conventional limits. Because the motoric aspects of speech production are so demanding, the requirement to produce conventional forms represents an enormous barrier to the child's learning of language. As a result, the forms of early words often deviate radically from the adult standard. The many simplifications that the 1-year-old introduces to adult phonology are well known to students of phonological development (Vihman and Croft, 2007). Children tend to drop unstressed syllables, producing *hippopotamus* as *poma*. They repeat consonants, producing *water* as *wawa*. And they simplify and reduce consonant clusters, producing tree as pee. These phonological processes echo similar processes found in the historical development and dialectal variation of adult language. What is different in child language is the fact that so many simplifications occur at once, making so many words difficult to recognize.

Early Semantics

Since Plato, scholars have considered the task of figuring out word meaning to be a core intellectual challenge. Quine (1960) illustrated the problem by imagining a scenario in which a hunter is out on safari with a native guide. Suddenly, the guide shouts 'Gavagai!' and the hunter, who does not know the native language, has to quickly infer the meaning of the word. Does it mean 'Shoot now' or 'There's a rhino' or perhaps even 'It got away'? Without some additional cues regarding the likely meaning of the word, how can the hunter figure this out?

The problem facing the toddler is similar to that facing the hunter. Fortunately, the toddler has some good cues to rely on. Foremost among these cues is the parent's use of joint attention and shared eye gaze to establish common reference for objects and actions. If the father says *hippo* while holding a hippopotamus in his hand, the child can use the manual, visual, verbal, and proxemic cues to infer that the word *hippo* refers to the hippopotamus. A similar strategy works for the learning of the names of easily produced actions such as falling, running, or eating. It also works for social activities such as *bath* or *bye-bye*. The normal child probably understands the role of shared eye gaze even before learning the first words. At 3 months, children maintain constant shared eye gaze with their parents. In normal children, this contact maintains and deepens over time. For autistic children, contact is less stable and automatic. As a result, autistic children may be delayed in word learning and the general growth of communication.

Shared attention reference is not the only cue toddlers use to delineate and pick out the reference of words. They also use the form of utterances to derive the meanings of new words. For example, if toddlers hear 'Here is a zav,' they know that *zav* is a common noun. However, if they hear 'Here is Zav,' then they know that *Zav* is either a proper noun or perhaps the name of a quantity. If they hear 'I want some zav,' they know that *zav* is a quantity and not a proper or common noun. Cues of this type can give a child a rough idea of the meaning of a new word (Tomasello, 2003). Other sentential frames can give an even more precise meaning. If the child hears, 'This is not green, it is chartreuse,' then it is clear that *chartreuse* is a color. If children hear, 'Please don't cover it, just sprinkle it lightly,' then they know that *sprinkle* is a verb of the same general class of cover. The use of cues of this type leads to a fast, but shallow, mapping of new words to new meanings.

As the child's stock of words grows, it becomes harder to keep words apart from each other. To solve this problem, children have to choose between two opposing strategies: overgeneralization and undergeneralization. It is extremely easy to detect overgeneralizations. If the child calls a tiger by the name *kitty*, there is clear evidence for overgeneralization. Undergeneralization is much more difficult to detect. For example, a child may use the word *dog* to refer only to the family dog and not to any other dog. Or a child may use the word *car* to refer only to cars parked outside a certain balcony in the house and not cars in any other context. Such undergeneralizations can only be detected if one takes careful note of the contexts in which a child avoids using a word.

Undergeneralizations are soon corrected, as they hear the relevant word used in a wider variety of contexts. Overgeneralizations can be corrected by supplying the name for the unknown object, such as the word *tiger* in the case of this example. In most cases, children are happy to learn these new names so that they can properly disambiguate things that are obviously so different as cats and tigers (Merriman and Bowman, 1989).

Word Combinations

Throughout the second year, the child struggles with perfecting the sounds and meanings of the first words. For several months, children produce isolated single words. However, eventually they need to go beyond his/her one-word level. They need to associate predicates such as want, more, or go with arguments such as cookie or mommy. The association of predicates to arguments is the first step in syntactic development. As in the other areas of language development, these first steps are taken in a very gradual fashion. Before producing a smooth combination of two words such as *my horsie*, children will often string together a series of single-word utterances that appear to be searching out some syntactic form. For example, a child might say *my*, *that*, *that*, *horsie* with pauses between each word. Later, the pauses will be gone and the child will say *that horsie*, *my horsie*. This tentative combination of words involves groping on both intonational and semantic levels. On the one hand, children must figure out how to join words together smoothly in production. On the other hand, they also must figure out which words can meaningfully be combined with which others.

As was the case in the learning of single words, this learning is guided by earlier developments in comprehension. We

have to assess children's early syntactic comprehension by controlled experiments in the laboratory. Here, as in the study of word learning, researchers have used the preferential looking paradigm. To the right of the child, there is a TV monitor with a movie of Big Bird tickling Cookie Monster. To the child's left, there is a TV monitor with a movie of Cookie Monster tickling Big Bird. The experimenter produces the sentence 'Big Bird is tickling Cookie Monster.' If children look at the matching TV monitor, they are reinforced and a correct look is scored. Using this technique, researchers have found that 17-month-olds already have a good idea about the correct word order for English sentences. This is about 5–6 months before they begin to use word order systematically in production.

The grammar of the first word combinations is extremely basic (MacWhinney, in press). The child learns that each predicate should appear in a constant position vis-à-vis the arguments it requires. For example, in English, the word more appears before the noun it modifies and the verb run appears after the subject with which it combines. Slot-filler relations can control this basic type of grammatical combination. Each predicate specifies a slot for the argument. For example, *more* has a slot for a following noun. When a noun, such as *milk*, is selected to appear with more, that noun fills the slot opened up by the word *more*. The result is the combination *more milk*. Later, the child can treat this whole unit as an argument to the verb *want* and the result is *want more milk*. Finally, the child can express the second argument of the verb *want* and the result is *I want more milk*. Thus, children build up longer sentences bit by bit, creating a more complex grammar. This type of word-based learning is present even in adults. In languages with strong morphological marking systems, word-based patterns specify the attachment of affixes, rather than just the linear position of words. In fact, most languages of the world make far more use of morphological marking than does English. In this regard, English is a rather exotic language.

Missing Glue

The child's first sentences are almost all incomplete and ungrammatical. Instead of saying, 'This is Mommy's chair,' the child produces only 'Mommy chair' with the possessive suffix, the demonstrative, and the copula verb all deleted. Just as the first words are full of phonological deletions and simplifications, the first sentences include only the most important words, without any of the glue. In some cases, children simply have not yet learned the missing words and devices. In other cases, they may know the 'glue words' but find it difficult to coordinate the production of so many words in the correct order.

These early omissions provide evidence for two major processes in language development. First, children try to make sure that the most important and substantive parts of the communication are not omitted. Unfortunately, children make this evaluation from their own, egocentric perspective. In an utterance like *Mommy chair*, it is not clear whether the child means 'This is Mommy's chair' or 'Mommy is sitting in the chair,' although the choice between these interpretations may be clear in context (Bloom, 1973). The second factor that shapes early omissions is phrasal frequency. Children tend to preserve frequent word combinations such as *like it* or *want some*. These combinations are often treated as units, producing errors such as 'I like it the ball' or 'I want some a banana.'

Productivity

Productivity can be demonstrated in the laboratory by teaching children names for new objects. For example, we can show a child a picture of a funny-looking creature and call it a *wug*. As we noted before, the positioning of the word *wug* after the article 'a' induces the child to treat the word as a common noun. Children can then move from this fact to infer that the noun *wug* can pluralize as *wugs*, even if they have never heard the word *wugs*.

Three-year-olds also demonstrate some limited productive use of syntactic patterns for new verbs. However, children tend to be conservative and unsure about how to use verbs productively until about age of 5 years. From the child's perspective, these laboratory experiments with strange new toys and new words tend to encourage a conservative approach. As they get older and braver, children start to show productive use of constructions such as the double object, the passive, or the causative (Brooks et al., 1999). For example, an experimenter can introduce a new verb like *griff* in the frame 'Tim griffed the ball to Frank' and the 5-year-old will productively generalize to 'Tim griffed Frank the ball.'

The control of productivity is based on two complementary sets of cues: semantics and co-occurrence. When children hear *a wag*, they correctly infer that *wag* is a count noun. In fact, because they also see a picture of a cute little animal, they infer that *wag* is a common, count, name for an animate creature. These semantic features allow them to generalize their knowledge by producing the form *wugs*. However, we could also view this extension as based on co-occurrence learning. The child learns that words that take the indefinite article also form plurals. On the other hand, words that take the quantifier some do not form plurals. In this way, the child can use both semantic and co-occurrence information to build up knowledge about the parts of speech. This knowledge can then be fed into existing syntactic generalizations to produce new combinations and new forms of newly learned words. The bulk of grammatical acquisition relies on this process.

The Logical Problem of Language Acquisition

The problem with productivity is that it produces overgeneralization. For example, an English-speaking child will soon learn to form the past tense of a new verb by adding one of the variant forms of *-ed*. This knowledge helps the child produce forms such as *jumped* or *wanted*. Unfortunately, it may also lead the child to produce an error such as *goed*. When this occurs, we can say that the child has formulated an overly general grammar. One way of convincing the child to reject the overly general grammar in which goed occurs is to provide the child with negative feedback. This requires the parent to tell the child, 'No, you can't say goed.' The problem here is that children seem to ignore parental feedback regarding the form of language. If the child calls a hamburger a hot dog, the parent can say, 'No, it is a hamburger.' The child will accept this type of semantic correction. But children are notoriously resistant to being corrected for formal grammatical features.

The fact that children tend to ignore formal correction has important consequences for language acquisition theory. In the 1960s, work in formal analysis convinced some linguists that the task of learning the grammar of a language was impossible unless negative feedback was provided. Since negative feedback appeared to be unavailable or unused, this meant that language could not be learned without some additional innate constraints. This argument has led to many hundreds of research articles exploring the ways in which children's learning places constraints on the form of grammar. Referring back to Plato's *Republic* and *the Allegory of the Cave*, Chomsky and others have characterized the task of language learning as a logical problem, much as Quine characterized the word learning Gavagai problem.

In fact, children have more resources available to them than Chomsky seems to suggest. Using these resources, the child can recover from overgeneralization without negative feedback. In the case of goed, everyone agrees that recovery is easy. All the child has to do is to realize that there is only one way of producing the past tense of go and that is went. In other words, the irregular form went comes to block production of the overregularized form goed. Here, recovery from overgeneralization is based on the competition between the regular pattern and the irregular form.

Consider another example. Suppose that a child decides that the verb *recommend* patterns like the verb *give*. After all, both verbs involve a beneficiary and an object being transferred. However, only *give* allows a double object construction, as in 'John gave the library the book.' Most people find 'John recommended the library the book' ungrammatical. One solution to this error is to avoid making it in the first place. However, a more general solution is to record the strength of the competing syntactic patterns. The correct way of saying 'John recommended the library the book' is to say 'John recommended the book to the library.' This correct formulation should be strengthened whenever it is heard. As the strength of the frame for the verb recommend grows in comparison to the ungrammatical frame, the use of the competing frame is blocked. This solution assumes that the child realizes that the two frames are in competition. It may be that reaching this realization requires some attention to syntactic form. However, this solution does not require children to pay attention to corrective feedback. Instead, they only need to attend to correct sentences and to make sure that they understand that these are competing ways of saying roughly the same thing.

Emergentist Accounts

In the 1980s, a sharp division existed between accounts of language acquisition that emphasized learning and those that emphasized innate knowledge of universal grammar. At the start of the twenty-first century, there is no longer a clear separation between alternative approaches. Instead, the challenge facing researchers is to formulate a set of mechanisms that is rich enough to account for the details of these emergent processes and that is grounded on the facts of human neurophysiology. To achieve this, many psychologists rely on the formalisms of neural network theory, which is also known as connectionism (Rumelhart and McClelland, 1986). This framework uses large numbers of units and the connections between these units to capture the patterns of language. This weblike architecture of nodes and connections is intended explicitly to resemble the structure of the human brain with neurons, synapses, and weights on synaptic connections. Neural network models have provided good accounts for the acquisition of morphology, phonology, and syntax (MacWhinney, 1999).

A major limitation of many current models is their failure to pay sufficient attention to the child's perspective on learning. In the late 1990s, researchers began to correct this problem. Models that rely on concepts derived from dynamic systems theory (Smith, 1999) and the theory of attention (Merriman, 1999) have proven useful in accounting for word learning by focusing on the ways in which concrete situations provide learners with cues. Newer formal models also relate word learning to children's physical control of their own body and their own perspective as a causal agent (MacWhinney, 2008). These new developments may also allow us to understand how language works to embed children into the fabric of social life (Nelson, 1998).

Conclusion

Language is a unique marker of humanity. It distinguishes the human species from the rest of the creation, and it allows us to share our thoughts and feelings. Language is the most complex skill that any of us will ever master. Despite this complexity, nearly every human child succeeds in learning language. This suggests that language is optimally shaped to mesh with the abilities of the human mind and body. On the one hand, the universals of human language match up with our neurological, cognitive, and physical abilities. At the same time, parents provide rich contextual and emotional support to guide children through the process of language discovery. By studying language learning, we learn more about universals of human language, the shape of social interaction, and the structure of the human mind.

Language and Ethnicity

Günther Schlee, Max Planck Institute for Social Anthropology, Halle (Saale), Germany

Abstract

After defining ethnicity and the ethnic group, this article states that language is usually high up on the list of features most often used as ethnic markers. When it is used as the sole or defining criterion of ethnic identity, the question of the relationship between language and ethnicity becomes tautological. Against this premature identification of linguistic group and ethnic group, cases of ethnic groups are cited which define themselves as such and are perceived as such by their neighbors and do not share one language. Other examples illustrate that there is no clear correlation between feelings of otherness/hostility and level of linguistic difference. The role of language and beliefs about language are discussed in the context of the evolution of the nation-state. Macro-categories like language families are also found to have a variety of roles in identity discourses. Some originally linguistic classifications are used with genocidal intention, although they lack a linguistic or historical foundation by modern academic standards. Written and spoken language can also have different meanings for ethnic identification. After acquiring a second language, communities may continue to use the old alphabet, also for the newly acquired language, or they may use the newly acquired writing system even for their original language.

As 'language' is defined elsewhere in this volume, only 'ethnicity' needs to be defined here before the relationship between the two is discussed.

Ethnicity is a form of collective identity, and thus belongs to the same class of phenomena as religious affiliation, lineage, clan, or class membership. It is the awareness of belonging to an ethnic group, and the belief that others belong to other groups of this kind. Ethnic groups differ from other groups, like voluntary associations or age-sets, by the following criteria: they comprise people of both genders and all ages, or, as Elwert (1989) puts it, entire families. Even where exogamy extends far beyond the nuclear family, ethnic groups comprise enough such exogamous units to guarantee self-sufficiency in biological reproduction: marriage partners can be provided within the ethnic unit. This means that ethnic groups have the potential to recruit members by birth, and, indeed, that is how they recruit most of their members. It does not mean that this is the only form of recruitment and that there is no ethnic conversion.

The criterion of self-sufficiency in biological reproduction sets the lower limit of the size of an ethnic group. The upper limit is set by the criterion of alterity. As ethnic groups define themselves and are defined in contradistinction to other such groups, an ethnic group can never comprise all of humankind. Ethnic groups tend to be medium- to large-scale human aggregates, typically ranging from thousands to millions. Many ethnic groups, including those which do not have a 'nation-state' to their name, exceed many independent states in the size of their populations. 'Ethnic group' and 'nation' form a pair of concepts, the first stressing cultural aspects, and the second political ones. 'Nation' includes the additional element of statehood in one or the other form. One can say that an ethnic group plus a state in which it predominates or a claim to such separate statehood is a nation. The fact that political rights like self-determination are attributed to nations in the political and juridical discourse does not help to define which ethnic group qualifies as a nation and which one does not. Any ethnic group can claim to be a nation and become one through such a claim. The only difference between a mere ethnic group and a nation without state is that the latter claims political sovereignty and the former does not necessarily do so. This distinction may not be very helpful in solving practical political issues, but social science does not provide a more helpful one.

Ethnicity is a cultural construct and its construction materials are cultural as well. There are other cultural constructs which are partly based on biological givens, like gender on biological sex, but in all cases in which ethnicity claims to be based on biological facts like discontinuities in the distributions of genes (race), such claims can be shown to be without a biological basis. Genes may cluster in different ways, but they never mark ethnic boundaries. Ethnic groups are never based on race, but very frequently on beliefs about race. Another element ethnic groups tend to attribute to themselves, often counterfactually, is a venerable age, and therefore ethnicity can in some ways be said to be a pseudo-biological category: ethnic groups view themselves as natural and stable over time like biological species. Other parts of culture, in addition to beliefs about race, which play a part in the construction of ethnic groups, include the reference to real or imagined historical events, peculiarities of customs, and the like. No two ethnic groups have a set of criteria which is alike, but typically ethnic discourses make reference to a plurality of such criteria. If only one such criterion is stressed, like religious affiliation, one would not speak of an ethnic group, but, rather, of a religious one.

For our present topic it is of special importance that language tends to be (but by no means always is) high up in the catalog of cultural criteria used to mark the boundaries between ethnic groups. This makes the question of the relationship between language and ethnicity appears tautological in some cases. Where language is used as the primary marker of an ethnic boundary (Barth, 1969), ethnic and linguistic units tend to be congruent. In post-World War I Europe, the language census has in numerous cases simply replaced the declaration of political will of local communities in effecting boundary corrections between nation-states (Dench, 1986). On the other hand, through the school system and the exclusive use of the majority language for administration, national languages or languages which enjoy a special status in certain areas have

been imposed on linguistic minorities (Gellner, 1981). Congruence between linguistic communities and ethnic units/nations has thus been promoted on the interstate level by adjusting political boundaries to language distribution areas and on the intrastate level by extending a language policy to the boundaries (e.g., Alsace-Lorraine, Silesia). In spite of the fact that these processes have been at work for some time, still only a small fraction of the world's nations is linguistically homogeneous (Ra'anan, 1989).

While in some cases ethnic and linguistic units are coterminous, at the other extreme we find ethnic units, well defined by other criteria, which have nothing to do with language. The Garre of northeastern Africa conceive of themselves as one ethnic group because of their common genealogy and clan organization, their shared pastoral nomadic culture, and their desire, not always fulfilled, to keep pace with each other. The Garre are divided into four linguistic clusters which crosscut other criteria of differentiation like clanship. Some of them speak an Oromo dialect close to the one of the Boran, while some speak Af Rahanweyn, yet others Af Garreh Kofar. The latter two are closely related Somali-like languages but are kept clearly apart by their speakers. There are also Garre who speak Somali proper. Oromo is a different language well beyond comprehension. It belongs to the same lowland branch of the East Cushitic languages as the Somali-type languages, but internal differentiation within this branch is high. The fact that the Garre are also divided between three nation-states (Kenya, Ethiopia, and Somalia) has nothing to do with this linguistic differentiation, since speakers of all four languages are found among the Garre of all three states. The only language which is spoken exclusively by Garre appears to be Af Garreh Kofar, but to the outside observer it is difficult to distinguish that language from Af Rahanweyn which is spoken by hundreds of thousands of non-Garre, namely Somali of the Rahanweyn clan-cluster. It does happen that Garre who do not share one of these Cushitic languages are obliged to converse with each other in languages from totally different language families, like Swahili (Bantu) or English (Germanic) which they have acquired at school, an institution frequented by only a minority of them for mostly short periods.

If there are enough other elements (political, economic, and cultural) on which a feeling of ethnic belonging and commonality is based, such an ethnic unit can tolerate a high degree of linguistic diversity. If these other foundations are absent, no amount of linguistic homogeneity can prevent disruption. Even within a language formerly perceived as one, now three different languages can be distinguished if the political will so dictates. This is exemplified by the split of the Serbo-Croatian language into Serbian, Croatian, and Bosnian.

The close association between a nation and its national language is a fairly recent development of political ideology even in Europe, and more so in other parts of the world to which this idea has been exported. Originally the term mother tongue (*Muttersprache*) referred to the language learned from the mother or wet nurse as distinct from the language of the male sphere, of officialdom and scholarship, i.e., Latin (Ahlzweig, 1994). Through romanticism and the evolving linguistic nationalism this term later acquired political overtones. The modern national states of Europe have, in their formative period, taken little account of the map of language distribution. Personalities claimed in retrospect as forerunners of German, Russian, or other nationalisms, in their real lives often preferred to speak French (e.g., Frederick II of Prussia, Tsar Peter the Great). The ethnicization of the state, its culturalization, and its evolving association with a particular language was a gradual process in the development of modern Europe. Linguistic obstacles were sometimes artificially raised between nations. As their national standard, the Norwegians have chosen from among their many dialects the one most different from Danish.

Not only languages but also language families have been politicized by identifying them with groups of people who were often ascribed racial characteristics, as a result of which they were either accorded privileges, or denied such privileges and even such basic rights as freedom and the right to live. Nowadays nobody outside the lunatic fringes would use the term Semite, to the extent that it is still used at all, in any other sense than speaker of a Semitic language. But there are other such terms of Biblical derivation like Cushites and Hamites which still continue in political careers which were unforeseen by the late eighteenth-, nineteenth-, and twentieth-century European historical linguists who applied them to clusters of languages they found to derive from shared ancestral forms. One can hear Oromo nationalists in Ethiopia arguing for the inclusion of minority groups and their territories into Oromia on the grounds that, although they are not Oromo, they are also Cushites. Ideologies about the repulsion of Hamitic intruders are at the root of the genocide against the Tutsi in Rwanda, although the Tutsi, in fact, speak the same Bantu language as their Hutu murderers, and historical theories that they ever spoke a different language are questionable to say the least. Ironically, too, the term Hamitic is no longer used by linguists. This may serve as a recent example that linguistic classifications, once they cross the boundaries of the academic sphere, can develop a dynamic of their own and that such a dynamic can be quite a murderous one.

Linguistic nationalism often appeals to romantic notions about the relationship between a particular language and other aspects of the culture of its speakers. The language we speak is believed to influence our thinking in a subtle way, giving language a much deeper cultural implication than that of a mere boundary marker between different cultural/ethnic units. Such ideas, which go back to Johann Gottfried Herder (1744–1803), cannot be explained away by pointing to the ways in which they are instrumentalized by nationalists. In Herder's view, a language is the 'collective treasure' of a nation and, since each language shapes the perspective on the world in a different way, the intellectual wealth of mankind consists in the diversity of its languages, i.e., in the number of such treasures (Schlesinger, 1991: p. 12f). Or, in the words of a modern Herderian: "It is ethnic and linguistic diversity that makes life worth living. It is creativity and beauty based upon ethnic and linguistic diversity which makes man human" (Fishman, 1989: p. 15). Very differentiated assumptions about the interrelationship between language and thought have also been put forward by Humboldt (1988), while a more simplistic view, basically a linguistic determinism, was proposed much later by Whorf (1962). Whorfians have also claimed the earlier Sapir as one of their persuasion and speak of a Sapir–Whorf hypothesis (i.e., one's thinking is both enabled and limited by the

structure of the languages we speak). A fuller analysis of the interrelationship of language and thought or language and cognition would go beyond the scope of an article on language and ethnicity (for a summary see Schlesinger, 1991).

The above-mentioned possibilities, that an ethnic group is completely coterminous and identified with the community of speakers of a certain language, and the opposite case, of a total lack of such a congruence and the absence of any association between an ethnic group and the language(s) spoken by it, are two extremes of a range of variation. Between these extremes we find language and ethnicity interacting in a great number of ways. To examine how language relates to ethnicity, and which languages/ethnic identifications persist in which functions in a plurilingual and culturally heterogeneous setting, i.e., to study the ecology of languages, the following variables need to be taken into account:

1. Demographic variables, like the sizes of language communities and their growth rates, and their compact or dispersed form of settlement including the forms of mixture with speakers of other languages;
2. Political and juridical variables, like the status of a language and the institutions in which it is used, and the presence or absence of ethnic stratification of the labor market with which language status often correlates;
3. Ethno-cultural variables, like the association of a language with a group's history or religion, and the potential of a language in terms of range of vocabulary and tradition of writing;
4. Interactional variables like communicational mobility and degree of multilingualism of speakers, specialization of the functions of speech varieties in diglossic and polyglossic settings, and routines of interactions between ethnic groups/speech communities;
5. Variations on topic, to explore the influence of different topics on the choice of a language;
6. Predominant/exclusive use of a language in the public/private sphere, and the linguistic distance between the languages in contact (Haarmann, 1986: p. 11ff).

This list is not meant to be exhaustive.

Some of these variables are illustrated. In contact situations, languages may undergo functional differentiation. The original language in bilingual communities may become restricted to sacral functions. Ethnicity and language choice should not be studied in isolation from other dimensions of social identity like gender and age. Minority people may revert in their old age to the language of their childhood, while their professional lives have been dominated by languages of wider currency (Dow, 1991). The past interaction between languages, their differences in potential and prestige in different semantic domains, and the relationships between the speakers of those languages and the cultural values attached to their ethnic identities are reflected by loanwords. Contrary to the widespread assumption that loanwords are typical for specialized concepts, these often extend far into the basic vocabulary and may designate parts of the body or kinship terms (Haarmann, 1986: p. 186ff; Schlee, 1994). In intensive language contact situations, borrowing is not restricted to the lexicon and there may be light or heavy structural borrowing (Thomason and Kaufman, 1988: p. 74f).

Written language and writing systems show a stronger tendency to be maintained as sacred, and/or symbols of ethnic identity, than does spoken language. Aramaic-speaking Christians became speakers of Arabic, which they also used for writing, and in which they produced a considerable literature, but for a long time they continued to use their earlier Syriac alphabet because they identified the Arabic alphabet with the Qur'an and Islam. The mirror case is provided by Muslims in the post-*Reconquista* Spain, who wrote Spanish in Arabic characters. Jews throughout Europe for centuries wrote the respective majority languages of the countries in which they lived, with a sprinkling of Hebrew words, in Hebrew characters. Where the new alphabet, like the Arabic alphabet in non-Arabic countries converted to Islam, is associated with holy texts, the opposite may occur. Many different languages have been written in the Arabic script, and other writing systems, some of them ancient, have fallen into disuse (Lewis, 1998).

Also linguistic variation within the performance of one speaker in the same speech act can highlight aspects of language and ethnicity. A narrator may switch in a story back and forth between languages and/or more or less standardized/creolized varieties of these languages to depict characters to whom different ethnic and other social identities are attributed. Also, in presenting themselves, polyglot people, or people who master more than one register of a language, can play with options of identification rather than being tied to one form of speech and the ethnicity, or more generally the identity, it connotes (LePage and Tabouret-Keller, 1985).

Switching and the need to choose a language are phenomena which occur only in polyglot settings. Moving from what happens within an individual to the global perspective, we notice that monolingual and polyglot settings are very unevenly distributed, or, put in a more gradualist fashion, that the number of languages per surface area varies a great deal if we move from one region to another. The number of languages is roughly correlated with the level of difference between them. Where we find many languages in the same area, often these represent different language families, or, when they are of the same family, they belong to quite different branches. Combining the number of languages with the levels of difference between them, we can say that zones adjacent to each other can differ a great deal in their linguistic diversity. Often linguistic fragmentation is found in rough territory, typically in mountain ranges. The many and often only quite distantly related Native American languages, which used to be spoken in the west of the United States would fit this pattern. But geography does not explain all of the variation. Mountains and other obstacles to communication seem to favor heterogeneity, and both the Alps and the Caucasus have a high level of diversity. But in the Alps we have just three language families – Romance, Germanic, and Slavic – which are all related to each other on the next higher level as Indo-European languages; and this is nothing in comparison to the levels of diversity we find in the Caucasus. And there are other high-diversity zones like the Lower Omo area of southwestern Ethiopia, which are flat or hilly at the most, and nevertheless have a smaller 'particle size' in everything from languages to clans and ethnic groups. There we find many Nilotic, Omotic, and Cushitic languages numbering only a few thousand speakers each.

In some cases this linguistic diversity is reflected by the political map, whereas in other cases it is not. Where linguistic and political units have a higher level of congruence, the causality behind this phenomenon may have worked in one direction or the other. Linguistic proto-nationalism may cause linguistically homogenous areas to unite politically, or the state may compose one language on its territory (e.g., Modern Greek 'Katharevousa') or develops incentive structures which cause one language to win. Applicants for the civil service in Kazakhstan, for example, have to be fluent in Kazakh, although in practice Russians still predominate in day-to-day administrative business. But this may change with the increasing number of Kazakh speakers in the administration.

But why is there a fragmentation belt with hundreds of languages belonging to three different macro-families across Africa roughly along the Sahel zone and the savannah belt south of it, while across north Africa even before the spread of Arabic only one language family (Afro-Asiatic) was clearly dominant and south of it the comparatively recent spread of Bantu languages covers most of the continent? The conditions which lead to the rise of diversity and its preservation are far from having been comprehensively explored.

Conclusions

Apart from all these riddles about higher and lower degrees of diversity, we also find some universals. One of these universal features of human beings is the capacity to deal with diversity. Since the disappearance of other human species such as the Neanderthal, we have been left alone. There are no other hominids apart from Homo 'sapiens sapiens.' Still, we seem to be biologically equipped to deal with a high degree of internal diversity. (Communication with other species, such as canines and ungulates, in a symbiotic system (pastoralism), would be a different topic, though not a less interesting one.) Stephen Levinson (2006) has proclaimed the existence of a human interaction engine. Starting from observations about 'first contacts' between people who have no knowledge about each other and do not share a language, and from his experience with deaf-mute people, he has come to the conclusion that human beings start to create sign systems instantly and spontaneously. How has this engine evolved? And why do we have the capacity to learn 10 languages or more, and why are we able to translate and interpret? Why do we possess the basic skills for doing anthropology? Nature does not pay for luxuries. These features must have offered an evolutionary advantage. (This human interaction engine must be something on the same level of generality as the 'ability to read and share intentions,' stressed by Tomasello et al. (2005: p. 690). It is one of the prerequisites for the development of languages and language-based complex collaboration. We cannot derive it from language, because it must have been there before.) The game we are studying, the game of identification and reidentification, of learning the features which define friend and foe, of manipulating these delineations, of asserting or hiding who we are, of expressing ourselves in one or the other code, thereby including or excluding people from our audience or defining those to whom we appeal for solidarity and those against whom we make these appeals, making group differences narrower or wider, might be a very old game. Playing this game well often was a matter of survival, and many who did not play well are no longer with us. We have evolved with this game and in response to it. Cultural and linguistic diversity is natural. It has existed for a long time, and we are biologically adapted to it.

Abstract

Gender is an important construct in all societies, involving the binary distinction male–female, and divisions made on the basis of what it is to be a woman or a man, and what is taken to be masculine or feminine. Language plays a key role in both constructing and sustaining these divisions. The study of language and gender has produced a body of diverse explanations for gender differentiation in language use. While early work on language and gender employed quantitative methods and categorized speakers according to biological sex, within recent research qualitative, ethnographic approaches have predominated as the field has witnessed a shift from viewing gender as a fixed social category to theorizing gender as a dynamic, performative social construct.

Gender is an important construct in all societies, involving the binary distinction male–female, and divisions made on the basis of what it is to be a woman or a man, and what is taken to be masculine or feminine. Language plays a key role in both constructing and sustaining these divisions. The study of language and gender has produced a body of diverse explanations for gender differentiation in language use. These differing, even conflicting, explanations reflect the theoretical developments in the discipline, as a shift has taken place from viewing gender as a fixed social category to theorizing gender as a dynamic, performative social construct. It is through tracing these developments and their corresponding explanations for how women and men speak that this article addresses the interplay between language and gender.

Sociolinguistic Variationist Studies

Early work on language and gender emerged from the sociolinguistic investigations of language variation in the 1960s and 1970s. Labov's (1966, 1972) social stratification studies examined particular linguistic variables in accordance with the social class and particular geographical location of their informants, assessing which speakers used the most prestigious, 'standard,' forms and which speakers used 'nonstandard' vernacular forms. What came to light from these studies was that as well as class, gender was affecting phonological and grammatical patterning. Labov found that in each social class, women used prestige forms more than men, and that this was particularly telling in the lower middle-class grouping. Identifying what he terms hypercorrection, or the overuse of prestige forms by the female speakers in that group, Labov argued that the lower middle-class females were insecure about their status and therefore hypercorrect in order to gain prestige. For the male speakers, Labov argued that there appeared to be connotations of masculinity associated with nonstandard forms in the male working-class group, suggesting that covert prestige was associated with the use of vernacular forms by the working-class male speakers. This notion of overt and covert prestige was investigated by Trudgill (1972) who reported that, like the female speakers of Labov's New York studies, the female speakers in his study in Norwich in the UK tended to use nonstandard, vernacular forms less frequently than the male speakers. Trudgill argued that these differences in language result from status-consciousness, with women being more status-conscious than men. According to Trudgill, women are more status-conscious because their social position is less secure than men, and therefore signaling one's social status linguistically may be more important for women.

Alternative explanations for gender differences in language use emerged from social network theory (Milroy and Milroy, 1978; Milroy, 1980). From this approach, the differences between speakers who use more prestige forms and those who use more vernacular forms result from group membership. Social network theory suggests that rather than social status, it is group pressures from within the communities in which individuals live and work that have the power to enforce linguistic norms, but that these vary among communities since individual speakers have differing amounts of social ties within a particular group; for example, in some communities it may be that men have a wide range of social contacts whereas women have fewer social contacts, while in other communities men may have more restricted social contacts than women. A further explanation for gendered differentiation in language use derives from what has been termed a market forces view (Talbot, 2010). From this perspective, economic factors are seen as the crucial determining factor which affects use of the prestigious or vernacular variants. Nichols (1998), for example, demonstrates that gender differences in employment require some speakers, but not others, to use more standard and less vernacular variants. The text often regarded as the foundation for the discipline of language and gender studies, however, is Lakoff's (1975) *Language and Woman's Place*. Lakoff's work heralds the first key development in the discipline: the approach categorized by the term the deficit approach (Talbot, 2010).

Deficit and Dominance

Lakoff (1975) claims that there is a distinct 'women's language.' According to Lakoff, as a result of sex-role socialization, where girls and boys learn to talk in ways appropriate to their gender,

females are socialized into using inferior language characterized by weakness, uncertainty, and excessive politeness. The use of such deficient language, Lakoff argues, disadvantages women and subjects them to linguistic discrimination. The features Lakoff identifies as characterizing women's language include lexical items, discourse particles, and intonation patterns. Lexical items comprise precise color terms such as teal green, affective adjectives such as adorable, and superpolite forms such as the avoidance of expletives and the use of euphemism. Discourse particles and intonation patterns include hedges and tag questions which mitigate the force of an utterance, rising intonation and emphatic stress. While influential in drawing attention to gender and language use, Lakoff's work has been robustly criticized. Methodologically, for example, Lakoff's study is flawed since her observations are based on anecdote, taken from her own observations with no recorded empirical evidence to support her assertions. Furthermore, a simple one-to-one correlation between form and function is problematic and easily challenged; Holmes (1984), for example, demonstrates that tag questions have different functions, including the expression of solidarity. However, the most fundamental problem with Lakoff's approach is that in characterizing women's speech as deficient, men's language is positioned as the norm. Despite its flaws, however, *Language and Women's Place* set the agenda for language and gender studies, and it is in response to this work that the second key development in the discipline emerged: the dominance approach.

The dominance approach to language and gender is typified by the work of Zimmerman and West (1975) and West (1984, 1998). Unlike the deficit approach, the dominance approach does not take the view that women's speech is deficient; instead women are viewed as oppressed by patriarchy. From a dominance approach, it is the significant social, economic, and political power that men have which results in women being dominated. Zimmerman and West (1975) recorded single-sex and mixed-sex interactions, examining elements of the sequential organization of conversation including turn-taking, interruptions, overlaps, and silences. They found that in single-sex interactions interruptions were uncommon, however in male–female interactions, interruptions were frequent, with men responsible for the overwhelming majority of interruptions. Zimmerman and West concluded that men dominate in mixed-sex interaction by breaching women's right to the conversational floor. In a later study, West (1984, 1998) continued the focus upon interruptions, but the empirical data in this study were taken from dyadic doctor–patient interactions. West's findings were that in the encounters between male physicians and their patients, the majority of the interruptions were physician initiated, however, in the encounters between female physicians and their patients, the majority of the interruptions were patient initiated. West concluded that the conventional asymmetry between doctor and patient interaction is reversed when female physicians are involved, suggesting that gender can take primacy over status. West and Zimmerman and West thus see interruptions as a way of enacting power, viewing asymmetrical patterns in women's and men's language use as enactments of male privilege. There have, however, been several criticisms leveled at the dominance approach. Researchers came to view the dominance model as becoming a deficit model, portraying men's speech as the norm and women's speech as deviant. Furthermore, the model of patriarchal power came to be seen as problematic, implying that all men oppress all women. This notion of patriarchal power effectively categorizes women and men into two homogenous groups one of which is powerful and the other powerless, and therefore fails to take into account variation in groups of men and groups of women. The most central reaction against the dominance approach, however, arose as researchers became increasingly unhappy with the negative portrayal of women perpetuated by the dominance approach. The third key development in language and gender studies, the difference approach, emerged from this dissatisfaction.

The Difference Approach

The difference approach to language and gender became popular in the 1980s and 1990s, and is considered to have originated with the work of Maltz and Borker ([1982]1998). The focus of Maltz and Borker's work is on the problems of miscommunication that they suggest existing research shows when women and men interact. Their approach to the issue of miscommunication was heavily influenced by Gumperz's (1982a,b) work on interethnic communication. Gumperz argued that if cultural backgrounds differ, then miscommunication will occur because individuals will be drawing upon divergent uses and interpretations of linguistic strategies. Maltz and Borker applied this conceptualization of miscommunication to mixed-sex interaction. According to Maltz and Borker, girls and boys are socialized into two different subcultures, and it is within these respective subcultures that girls and boys learn to become competent speakers. Since girls and boys will thus develop different communicative norms, mixed-sex interaction should be seen as cross-cultural communication and miscommunication will therefore frequently occur. According to this view, women and men characteristically draw on different linguistic strategies: while women orient themselves to the person they are talking to such as through the use of personal and inclusive pronouns and actively seeking and giving back-channel support, men's speech is characterized by verbal posturing, capturing an audience through storytelling and arguing in order to assert dominance.

Researchers working on single-sex interaction have found the difference model particularly useful. Coates' (1988, 1996) work on all-female interaction provides a prime example of the difference approach. Coates argues that one of the key distinctions between male and female communicative styles is that men's conversation style is based on competitiveness whereas women's conversational style is based on cooperativeness, and her work on all-female interaction identifies numerous examples of this cooperativeness. According to Coates, the difference approach is necessary when analyzing single-sex interaction, since examining the speech of groups of all female speakers as simply the talk of an oppressed group misses the complexities and the strengths of women's talk, and makes it particularly difficult to positively reevaluate female speech styles.

Tannen's (1990) work on the difference between female and male linguistic performance is based on Maltz and Borker's two cultures theory. According to Tannen, in mixed-sex interaction individuals interpret the linguistic performance of others according to their own subcultural norms. As men and women thus evaluate utterances in disparate ways, miscommunication occurs. Tannen puts forward a number of dichotomies in her explanation of these communicative difficulties. Such dichotomies include status versus connection, whereby through engaging in conversation men expect to establish status in a hierarchy whereas women seek to establish connection and intimacy, and report talk versus rapport talk, where men are concerned with the exchange of information during talk, while women are concerned with building rapport. In order to understand each other better and to create more harmonious relationships, Tannen argues that women and men simply need to learn each other's subcultural linguistic norms. Tannen's book has, however, been widely criticized for its lack of attention to power differences. Cameron (1998), for example, points out that Tannen's approach is based on the notion that change will simply occur if men and women learn to understand the differences in each other's linguistic behavior, but, she argues, this fails to acknowledge that power roles are constitutive of gender differentiation. Although the difference approach has been valuable for language and gender research as it allows for a positive reevaluation of the speech styles that have been associated with women, in recent years the way in which gender has been conceptualized within the field has involved moving away from the binary opposition of male and female and seeing difference as the major goal of language and gender research.

The Dynamic Approach

The most recent approach to language and gender views gender as a dynamic, active concept. Rather than perceiving individuals as being of a particular gender, individuals are perceived of as doing gender. This shift from seeing gender as a verb rather than a noun moves analysis on from seeing gender as something that is simply learned during childhood socialization to a perspective from which gender is a constant process of performance.

Performativity

Butler's (1990, 1993) work on gender and performativity has been particularly influential in recent language and gender studies. According to Butler, gender is a repeated performance: "[t]he materiality of sex is constructed through a ritualised repetition of norms" (1993, p. x) However, this performance does not mean that one can perform anything one wishes, since, as Butler argues, "a wilful and instrumental subject, one who decides on its gender is clearly not its gender from the start and fails to realise that its existence is already decided *by* gender" (1993, p. x). Gender as a performative social construct, or the repeated performance of a range of behaviors associated with a particular sex, is therefore, for Butler, a constant process, as it is with preexisting gender norms that individuals negotiate. This move from binary oppositions to a more sophisticated conceptualization of gender has led to more nuanced concerns with the ways that individuals reaffirm, negotiate with, and contest what they hypothesize as appropriate behavior in particular contexts. The notion of a community of practice (henceforth CofP) has been particularly important for language and gender researchers in thinking through the concept of individuals negotiating, confirming, and attesting practices and interpretations in local contexts, developing a sense of their own gendered identity.

Communities of Practice

The CofP approach was first introduced into language and gender studies by Eckert and McConnell-Ginet (1992a,b). Eckert and McConnell-Ginet define a CofP as a group of people who are brought together through a joint engagement on a task and who, in so doing, jointly construct a range of speech styles, ways of interacting, and shared meanings. From a CofP perspective, individuals belong to multiple and wide-ranging CofPs, for example, at home, at work, in one's hobbies and interests, and therefore an individual's gender identity is fluid and variable, produced and reproduced during social interaction within these different CofPs. Indeed, in much work which takes the CofP as its methodological approach, the construction of identity as plural and variable has been a central analytical focus (for example, Bucholtz, 1999; Eckert, 2000; Mendoza-Denton, 2008). The CofP model allows for variations in women's and men's speech rather than making global, homogenizing statements, as there has been an observable move from large-scale quantitative studies such as those conducted by Labov to qualitative, ethnographic studies.

Indirect Indexicality

Many studies of language and gender which focus upon interaction have found the notion of indirect indexicality (Ochs, 1992) useful for overcoming the problematic correlation of linguistic form, function, and the sex of the speaker evidenced in earlier approaches (e.g., Kiesling, 2003; Mullany, 2007). In her work on indexicality, Ochs (1992) argues that the relation between language and gender is mediated through a web of social meanings. Direct indexicality is defined as language use where gender is explicitly encoded by linguistic items such as *Mr*, *Miss*, *boy*, *girl*, *man*, *woman*. Indirect indexicality is defined as language use where particular linguistic styles are encoded with stereotypically gendered meanings. From this perspective, the association of women with tag questions, for example, or the expectation that women are more linguistically polite than men operates only as *ideological* expectations.

Discourses of Gender/Gendered Discourses

Poststructuralist theory has been heavily influential in language and gender scholarship, most notably the work of Michel Foucault (1972, 1979, 1981) and his conceptualization of discourse as social practice. According to Foucault, discourses are "practices that systematically form the objects of which they speak" (1972, p. 49). On this view, Cameron and Kulick (2003, p. 16) argue, discourses are to some extent

"language-dependent practices of definition, classification, explanation, and justification"; in other words, socially constructed bodies of knowledge. As Mills (2004) points out, a discursive structure can be identified by the stability and regularity of the ideas, opinions, concepts, ways of thinking and behaving which are formed within a particular context and that act as a form of social control. According to Foucault, then, discourses structure the individual's sense of reality, of the world, of oneself, and of others, and therefore the ordering human beings impose on the world is through the categorization and interpretation of objects and experiences according to the discursive structures available to them. In terms of gender, Mills (2004) points out that discourses of femininity and masculinity demarcate the boundaries within which women and men perform their gender identities. Influenced by Foucault's conceptualization of discourse, Coates (1997, p. 311), for example, argues that there are competing discourses of femininity in circulation, she argues "there is no single unified way of doing femininity, of being a woman …different discourses give us access to different femininities…we are unwittingly involved in the ceaseless struggle to define gender." Taking the view that there is a potential multiplicity of femininities and masculinities that individuals take up, reject, or negotiate with has allowed researchers to produce more sophisticated analyses of how gender is constructed in both spoken and written data.

New Directions

The CofP model continues to be a popular approach to the study of language and gender in the twenty-first century. However, Mills and Mullany (2011) have pointed out that at present few studies relate the norms established within the particular CofP under study to wider social norms, therefore future research is needed which attempts to relate small-scale, local studies to their wider social context. An even wider, international perspective is also being developed within the field. Not only is research widening to non-English-speaking communities, but also in her work on language, gender, and globalization, McElhinny (2007) highlights the necessity for language and gender research to attend more thoroughly to the study of the articulation of language, gender, and various aspects of global economy. As the construction and negotiation of gender and the central role language plays in this construction become increasingly more complex and multifaceted, language and gender research continues to develop more nuanced approaches to the study of the interplay between language and gender.

Language and Labor Market Success

Ingo E Isphording, IZA – Institute for the Study of Labor, Bonn, Germany

Abstract

This article summarizes three different strands of the literature that address the labor market effects of language-related human capital: (1) A general importance is demonstrated in the empirical evidence on earnings and employment effects of literacy as the ability to productively use written information. Significant effects are found for developed and developing countries, leading on an aggregated macrolevel to a positive relationship between literacy and economic development; (2) The ongoing globalization leads to an increased demand for foreign-language proficiency to reduce search and information costs and overcome cultural barriers in the trade of services and goods and tourism. Against the background of scarce skill supply, employers are willing to pay significant wage premia, especially for global and local lingua franca; (3) For international migrants, destination language skills display both a prerequisite for and outcome of successful integration. Investments into destination language skills are highly rewarded by wage returns and higher employment probabilities and act as the medium of translation to apply premigration human capital in the destination country labor market.

Introduction

Proficiency in a language is one of the most basic parts of an individual's human capital portfolio. The productive functions of language are manifold, in both the labor market and everyday life. Language is used to express one's emotional status, providing the counterpart with necessary information on the otherwise unobservable inner state of mind, as well as expressing one's own identity and demands. Language is used as the main medium of social interaction. While this interaction does not necessarily contain any information conveyed, it provides the basic conditions for a productive environment. Language is the medium used for the record-keeping, organization, and processing of information and facts. Finally, the concept of linguistic determinism in linguistics states that language determines the way in which individuals are able to think and structure their own thoughts (Crystal, 2010).

The importance of language skills in the labor market has been growing during recent decades, in a process that is likely to continue for some time. The reduced demand for manual labor and the ongoing transformation of the labor market toward increasingly information-based production have drastically increased the need for language and literacy skills. Especially with the emergence and diffusion of information and communications technology usage into any niche of the labor market, there are hardly any occupations do not require a minimum of speaking, writing, and reading skills.

Possessing a sufficient level of literacy and language proficiency is far from being self-evident. Literacy rates across countries differ substantially, with an even greater heterogeneity within countries. Literacy and language proficiency are crucially related to socioeconomic status, education, health, and nativity. This interrelationship between an individual's socioeconomic environment and the language-related human capital introduces a large heterogeneity in language skills. Given the productive value of language skills, this heterogeneity is likely to be translated into labor market disadvantages for individuals possessing insufficient levels of literacy and language proficiency.

This article aims to provide an overview of the empirical evidence on how literacy and language skills depend on socioeconomic characteristics and affect individual labor market outcomes. The empirical evidence is summarized via three different angles that have gained attention in the literature: Section Literacy and Productivity deals the importance of language in general, as the main medium of communication, recording and storing of information, and the expression of demands; Section Foreign Languages in the Labor Market summarizes the literature on the importance of foreign languages in modern interdependent economies; and Section Destination Language Skills of Migrants provides an overview on the literature on the importance of the destination language acquisition of immigrants for the economic and societal integration. Finally, Section Conclusion concludes.

Literacy and Productivity

As the main medium of everyday communication, language plays a naturally important role in shaping the economic success of an individual, although the analysis of determinants and labor market advantages of skills in one's own mother tongue lacks a natural theoretical framework and is ultimately data-driven. Language skills in one's mother tongue affect the productivity in the work place in the form of literacy. UNESCO defines literacy as:

> the ability to identify, understand, interpret, create, communicate and compute, using printed and written materials associated with varying contexts. Literacy involves a continuum of learning in enabling individuals to achieve his or her goals, develop his or her knowledge and potential and participate fully in community and wider society.
>
> UNESCO, 2004

Literacy therefore represents the productive functions of one's language ability. In recent years, the data availability on the relationship between adult literacy and labor market

outcomes has improved substantially. In particular, the OECD has pushed forward data collection on literacy skills, with three subsequent international surveys now collecting literacy scores based on test booklets, as well as comprehensive information on socioeconomic living conditions: the International Adult Literacy Survey (IALS) conducted in 1994–98, the Adult Literacy and Lifeskills (ALL) Survey conducted in 2003–08, and the Program for the International Assessment of Adult Competencies (PIAAC) conducted in 2012. These data sets provide the basis for a range of studies analyzing the determinants and labor market effects of adult literacy.

The evidence suggests that basic literacy skills are associated with distinctive wage premia. McIntosh and Vignoles (2001) provide estimates for positive wage and employment effects for UK, noting that around 20% of the British population had severe literacy difficulties in 1999. These literacy difficulties are associated with a sizable wage penalty of about 15%. Using Canadian data, Charette and Meng (1998) show that literacy has a significant positive effect on wages, with their findings indicating that literacy is closely associated to formal education. Nonetheless, the wage effect goes beyond the returns of formal education, with literacy skills providing additional information in explaining wage differentials.

The relationship between literacy and economic well-being holds specific importance for developing newly industrialized countries, given that literacy is crucially dependent on a well-developed and functioning education system. Therefore, developing countries might display significantly lower-literacy rates than developed countries, although appropriate data are scarce in these countries. de Baldini Rocha et al. (2011) analyze the effect of literacy on earnings in Brazil, finding both significant employment and earnings effects of becoming literate. This evidence on the microlevel is complementary to macro-evidence on the relationship between literacy rates and the economic development of regions and countries. Aggregated literacy rates provide insights into the human capital stock of a country. Coulombe and Tremblay (2006) use data from the IALS study to explain the growth of 14 OECD countries by the literacy of labor market entrants. They show that literacy has a significant positive effect on growth indicators and conclude that raising the average level of literacy (e.g., by investing into women's education) is more important than focusing on high levels for restricted groups. Hanushek and Woessmann (2008) provide an overview of the relationship between cognitive skills (including literacy), individual labor market outcomes and economic growth, highlighting the importance of educational policy measures for countries' development. Following this importance for the economic development of countries, literacy has entered the UN Human Development Index as a main dimension of measurement.

Foreign Languages in the Labor Market

In an increasingly interconnected globalized world, international communication plays a growing and crucial role as a prerequisite for international factor movements, international trade, foreign direct investments, financial flows, and human migration. This leads to a worldwide growing demand for foreign language proficiency that is not always met by skill supply.

The acquisition of reading and speaking skills in a foreign language can be modeled as the economic decision weighing off the expected benefits and costs of speaking a new language. Formalized models are provided by Selten and Pool (1991) and Church and King (1993). The expected benefits of speaking a new language combine utility gains through being able to communicate in a certain language. The benefits and incentives of learning a new language can be divided into internal and external motivations. Internal motivations mainly refer to the nonmarket value of languages. Speaking a new language offers potential utility gains through easier access to new information and an increased population of potential communication partners. Furthermore, it also offers increased reputation, prestige, and recognition among peers. For some, the learning process itself might lead to utility gains through being a joyful process.

From an economic perspective, this nonmarket value of languages is accompanied by a market value related to the relative importance of a language to a country. This relative value is dependent on a range of factors: it is shaped by the applicability of a language in direct communication with foreign customers in tourism and services. Its value is related to its potential in international trade to reduce search, translating information costs when dealing with foreign information. In particular, the latter role of languages in shaping international trade flows has gained significant attention in the economic literature. Although English acts as lingua franca in modern international trade, knowledge in the trade partner's original language remains a crucial variable, especially in the development of long-term business partnerships and overcoming further cultural hurdles. Further, lower-linguistic barriers ease the promotion of trade and commerce by immigrants through easier access to the destination country, as discussed later in Destination Language Skills of Migrants. A range of studies proxies these linguistic barriers by summary statistics of linguistic distance between two trade partners, using grammatical information (Lohmann, 2011) or information on pronunciation of word lists (Isphording and Otten, 2013). Common findings of these studies are significantly reduced trade flows by higher-linguistic hurdles.

On the microlevel, language barriers are translated into expected benefits of learning a new language by the willingness of employers to pay for foreign language proficiency. Individuals have to weigh these potential utility gains from learning a new language against the costs associated to the language acquisition. These costs come in terms of direct monetary costs for language classes and indirectly by spent effort and foregone wages. The size of the costs is related to a range of correlates. Apart from a fundamental and unobservable heterogeneity in the ability to learn languages, the difficulty of learning a new language is influenced by the dissimilarity between the first language and the acquired language. Dissimilarities between languages raise large barriers in the acquisition process. While it might be comparably easy to learn a language from one's own language family (e.g., German, English, and Swedish from the Germanic language family, or Romanian, Spanish, and Italian sharing the Romance language family), the acquisition becomes much more difficult for linguistically distant languages, e.g., for a European attempting to learn Mandarin or Japanese. Isphording and Otten (2013) provide an extensive

analysis of the role of linguistic borders in language acquisition. Another crucial determinant of the costs of language acquisition is the age at which the language acquisition takes place. Linguistic and neurobiological research has identified a crucial 'critical period' in early adolescence until when language acquisition takes place almost effortlessly. The ability to acquire new languages subsequently decreases, in a process that continues into adulthood. As second-language education is typically associated with secondary schooling, most of the foreign-language acquisition takes place after this critical period. Acquiring a new language in adulthood faces an even more reduced ability to learn.

A rational and utility-maximizing individual will weigh these costs of language acquisition against expected benefits of speaking the new language. Ginsburgh and Prieto-Rodriguez (2011) provide an overview on returns to foreign languages in the EU. Their results indicate distinctive wage premia paid for foreign languages, with a strong heterogeneity across different countries and the wage distribution. Knowledge of foreign languages mainly pays off in high-skilled occupations. While English as the main lingua franca is rewarded in any country, in Southern European countries it competes in importance with Romance languages, which seem to play the role of local lingua franca, such as French in Spain. This importance is backed up by Isphording (2013), who estimates large returns to foreign-language skills within a sample of immigrants in Spain. Again, the highest returns are paid for English skills, closely followed by the returns to French skills.

Furthermore, Williams (2011) finds significant positive returns to foreign-language skills in Western European countries, which he relates to the importance of incoming tourism from specific language groups. Here, a similar logic as in the case of international trade applies, whereby tourism flows increase the applicability of language skills in the service sector, as well as employers' willingness to pay for proficiency in a specific language.

Destination Language Skills of Migrants

The best-researched field regarding the labor market effects of languages is the importance of destination language skills of international migrants. Language skills are the most important and visible part of the human capital an immigrant acquires during his or her migration history. The consideration to invest into proficiency in the destination country language heavily influences the economic success in the host country. However, even prior to the migration decision, the expected costs of later language acquisition, e.g., in the form of perceived linguistic borders, shape the initial decision to migrate itself, thereby influencing aggregated migration flows along linguistic borders (Adsera and Pytlikova, 2012).

As the decision to invest in the destination language is a conscious one (contrary to the acquisition of a first language, but similar to the acquisition of foreign languages discussed in the former section), it is appropriately analyzed in a human capital framework, weighing off expected benefits and costs of the language acquisition. Chiswick and Miller (1995) distinguish the determinants of language fluency of immigrants into three categories related to the exposure to the destination language, the efficiency in learning a new language, and the economic incentives derived from being able to communicate in the destination language. Exposure and learning efficiency, dependent on individual, institutional, and situational characteristics, shape the costs in terms of effort or monetary costs for language classes, while economic incentives display the expected benefits formed by increased opportunities for economic integration and social participation.

The exposure to the destination language can be divided into prior to and postmigration exposure. Prior to migration, emigrants might learn about the destination language by being educated in secondary school and reading nontranslated literature and watching dubbed movies. Postmigration, exposure to the destination language will mainly be a nondirected process dependent on the time of residence in the country. The exposure is also dependent on an individual's socioeconomic situation, with the labor market status, working full-time, being unemployed or out of the labor force, influencing the degree of exposure. The decrease in exposure when individuals are not or unemployed is especially pronounced when living in a socioeconomic enclave. Such a linguistic enclave further reduces incentives to acquire proficiency in the destination country by restricting the range of opportunities where this language can be applied.

Immigrants differ in their ability or efficiency in acquiring the destination language. This ability is shaped by cognitive ability, education that might be influenced by selection processes in migration. A major factor influencing the ability to learn new languages is the age at arrival, given that this determines the ability to acquire the new language according to the linguistic-based critical period hypothesis discussed earlier. Immigrants arriving in young ages before this critical period in early adolescence pick up the destination language almost effortlessly and reach a near-native level of proficiency. For immigrants arriving after the critical period, the ability to learn new languages is distinctively decreasing.

A second linguistically based factor influencing the ability to acquire proficiency in the destination language is the linguistic distance between the mother tongue and the language to acquire. The linguistic origin turns proves a major determinant of destination language proficiency, outweighing further socioeconomic correlates and determinants. The effect of linguistic distance interacts with the effect of age at arrival: while young immigrants are unlikely to be affected by their linguistic origin, the additional costs in the language acquisition associated to a distant linguistic origin are substantial for later arrivers who start acquiring the new language after the critical period (Isphording and Otten, 2013).

The third group of influencing factors (besides exposure and efficiency) constitutes the economic incentives of language proficiency in the destination language. The willingness to invest into the language proficiency mirrors the expected benefits. While parts of these benefits and utility gains will be due to an increased potential in social and cultural participation, economists tend to focus especially on labor market advantages.

The estimation of labor market effects of language skills is confounded by a number of empirical pitfalls, measurement error, unobserved variable bias, and simultaneity. First, with objective assessments of language skills being a rare exception,

studies addressing the destination language proficiency of migrants are typically restricted to self-reported information on language skills. This subjective information is likely to be prone to a severe measurement and misclassification error. Second, analogously to the estimation on returns to education, estimates for effects of language proficiency are likely to be biased by omitting unobservable ability from the regressions. Both wages and language skills are potentially positively affected by an unobservable (to the researcher) ability.

Recent studies have attempted to address these empirical issues by instrumental variable regressions. This technique relies on the assumption that there exists an observable variable that affects the language acquisition but is unrelated to the sources of the empirical pitfalls, namely the measurement error, the unobserved ability, and the labor market outcomes itself. With this instrument variable, exogenous levels of language skills can be predicted, which are then used to estimate the actual effect of language proficiency.

Due to the omnipresence of language in everyday life, such an instrument variable is hard to find. Initially, Chiswick and Miller (1995) proposed using parental education, family composition, and family ties abroad as valid instruments. Their estimates for the US, Canada, and Israel indicate severely downward biased ordinary least squares (OLS) estimates, but distinctive wage premia estimated by IV between 30 and 50% for speaking English 'Well' or 'Very Well.' Dustmann and Van Soest (2002) attempt to address the measurement error by using time-adjusted averages and lags and leads of self-reported measures of language proficiency from panel data of the German Socio-Economic Panel. Their sample is restricted to German 'guest workers,' immigrant blue-collar workers from Mediterranean countries, enlisted to fulfill the excess labor demand after World War II. They conclude that estimates from uncorrected OLS regressions are severely downward biased. Their results indicate a wage premium for speaking German 'Well' or 'Very Well' by about 11–14%, which exceeds the OLS estimates by a factor of 2–3.

Using data from the 1990 US Census, Bleakley and Chin (2004) focus on childhood immigrants in the United States who arrived at an age younger than 17. Their identification relies on the so-called critical period of language acquisition, based on the empirical evidence of a decreasing ability to learn languages after reaching adolescence. Linguists and neurobiologists state that children are able to acquire a language effortlessly up to a native level until this critical period, while this ability decreases distinctively thereafter. Bleakley and Chin use this structural break to compare young and old arriving immigrants, while additionally controlling for whether the immigrants originates from an English- or non-English-speaking country. By using this double comparison groups, they again state that uncorrected OLS estimates are severely downward biased. In their estimates, an increase in language ability on a 0–3 scale (0 = not at all, 3 = Very well) is associated with a wage premium of around 30%. Using more recent data from the American Community Survey 2010, Isphording and Sinning (2012) extend their analysis to the overall population of immigrants in the United States, substituting the age at arrival with the exposure to English by time of residence. Their results confirm the initial results for child migrants and for both child and adult migrants.

While these causal IV estimations provide a robust estimate of the importance of language skills for the economic integration of immigrants into a host country, they provide little insight into the channels through which the language skills affect labor market outcomes. Indeed, only a few studies have gone into detail in this regard. Bleakley and Chin (2004) identify schooling as a major channel through which language skills affect the earnings of child migrants. Child migrants from non-English-speaking countries arriving in early years possess on average 2 years of additional schooling compared to their late-arriving counterparts. The additional schooling is able to explain almost the complete causal effect of language on wages. Isphording and Sinning (2012) confirm the importance of education as a mediating channel for child migrants, although their results neglect this importance for immigrants arriving in adulthood (who acquired their education in the sending country).

Chiswick and Miller (2010) address the occupational choice of immigrants regarding the language requirements of occupations as a mediating channel of language skills on wages. They combine data from the 2000 US Census with scores for English requirements measures taken from the O*NET database. Their results indicate a strong effect of language probability on the job choice, whereby good job matches in terms of language skills and requirements are rewarded by wage premia. Berman et al. (2003) use Israeli survey data to assess a potential complementarity between immigrant language proficiency and further human capital. Their results indicate a strong heterogeneity in the effect of language proficiency on wage growth across occupations. As the language acquisition is only relevant for high-skilled professions, the authors interpret this as evidence for the complementarity between language proficiency and further human capital. Chiswick and Miller (2003) use 1991 Canadian Census data to show a similar complementarity between premigration schooling and experience and the destination language skills. Language skills act as the translating medium to apply premigration acquired human capital into the host country labor market.

Aside from these studies focusing on the earnings effects of wages, further studies have shown additional effects of language proficiency on labor-market related outcomes. Aldashev et al. (2009) document the impact of German language use on labor supply decisions and unemployment probability using German household data from the Socio-Economic Panel. They conclude that language proficiency significantly affects the probability of labor market participation and subsequent employment. Dustmann and Fabbri (2003) analyze the language skills of ethnic minorities using UK survey data. Besides significant earnings effects, they also find a higher employment probability of around 20% for individuals who are proficient in English.

Finally, besides heterogeneity in the level of proficiency, a second mechanism can arise through which language differences can affect labor market outcomes. Differences in language do not necessarily mean vertical differences in proficiency, but can also appear in the form of a horizontal differentiation through dialects or accents, speech patterns, or choice of words. These differences can act as a signal providing information on social status and ethnicity and allow for taste-based or statistical

discrimination. Grogger (2011) provides evidence of an influence of racial speech patterns in the United States. Using unique data from the 1997 National Longitudinal Survey of Youth (NLSY) augmented with anonymously rated speech patterns, he identifies a significant wage penalty of around 12% for speaking African-American English instead of standard American English.

Conclusion

This article aimed at providing an overview of the economic literature addressing the relationship between language and productivity. Three different strands of literature have been summarized: (1) studies addressing the literacy of the native population and its effect on individual labor market outcomes and aggregated growth and development; (2) the labor market effects of foreign language proficiency against the background of a growing demand by globalization; and (3) the importance of destination language proficiency for the social and economic integration of immigrants.

All three strands of the literature provide comprehensive evidence for the crucial role played by language-related human capital in economic processes. As the key medium of communication, language crucially shapes economic outcomes on both the individual and aggregated level.

The general importance of language-related human capital becomes apparent with empirical evidence on the labor market effects of adult literacy. For both developed and developing countries, studies demonstrate a positive effect of literacy on wages and employment probabilities that go beyond the effect of associated formal education. This microevidence is accompanied by macroevidence linking the economic growth to literacy rates as a crucial driver of economic development.

The specific importance of language in the labor market has been fueled by ongoing globalization. International trade in goods and services, tourism, and migration flows increase the importance of foreign-language skills. Foreign-language skills are crucial in reducing search and information costs, as well as establishing long-run business relations. This is especially true for English as the commonly accepted lingua franca in international trade. Proficiency in foreign languages is rewarded by employers though significant wage premia, especially in occupations related to services, trade, and tourism.

Finally, the best-researched field against the background of language skills and the labor market is the importance of destination language skills for international migrants. The proficiency in the destination country is both a prerequisite for and an outcome of a successful integration into the host country. Immigrants weigh off costs and expected benefits to decide on their investment in terms of the effort and opportunity costs of language acquisition. Determinants of language skills, such as linguistic origin, age at migration, individual education and ability, and enclave density, shape a heterogeneous cost structure, while expected benefits are given by labor market advantages, in terms of higher wages and employment probabilities. Wage effects of language skills are heterogeneous across the occupational distribution, with requirements for language skills strongly differing between blue- and white-collar occupations. Language skills are shown to be complementary to further forms of premigration acquired human capital, acting as the medium of translation to apply home-country knowledge in the host-county labor market.
